**Guide to authors**

● Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.

● Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.

● Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.

● 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the *Système International*. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; exp (*a*) is preferred to  $e^a$  if '*a*' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note: (i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth ed. (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unlettered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely.

Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

*Nature's* publishing policy is outlined in 258, 1 (1975) and 264, v, 11 Nov. (1976).

Carbon dioxide reversibly abolishes ionic communication between cells of early amphibian embryo	L. Turin and A. Warner	56
Unique cytoplasmic phosphoproteins are associated with cell growth arrest	R. F. Kletzien, M. R. Miller and A. B. Pardee	57
Tumour-dormant states established with L5178Y lymphoma cells in immunised syngeneic murine hosts	K. J. Weinhold, L. T. Goldstein and E. F. Wheelock	59
Post-infection genetic resistance to avian lymphoid leukaemia resides in B target cell	H. G. Purchase, D. G. Gilmour, C. H. Romero and W. Okazaki	61
Two mechanisms of migration inhibition factor induction by tumour antigens	S. Landolfo, R. B. Herberman and H. T. Holden	62
Correction of human mucopolidosis II enzyme abnormalities in somatic cell hybrids	M. J. Champion and T. B. Shows	64
Calcium ion regulates chemotactic behaviour in bacteria	G. W. Ordal	66
Histamine induces release of an eosinophil immobilising factor from mononuclear cells	E. Kownatzki, G. Till, M. Gagelmann, G. Terwort and D. Gemsa	67
Dark noise in retinal bipolar cells and stability of rhodopsin in rods	J. F. Ashmore and G. Falk	69
Acetylcholine receptor conformational transition on excitation masks disulphide bonds against reduction	P. D. Bregestovski, V. I. Iljin, O. P. Jurchenko, B. N. Veprintsev and C. A. Vulpius	71
Cellular regulation of an allosteric modifier of fish haemoglobin	G. S. Greaney and D. A. Powers	73
Thyroidal trophic influence on skeletal muscle myosin	D. Ianuzzo, P. Patel, V. Chen, P. O'Brien and C. Williams	74
Hydrolysis of polyesters by lipases	Y. Tokiwa and T. Suzuki	76
Involvement of DNA gyrase in bacteriophage T7 DNA replication	T. Itoh and J.-I. Tomizawa	78
Is the centriole bound to the nuclear membrane?	M. Bornens	80

## INDEXES

The following indexes are still available:

	UK	Rest of World
1971	£4.00	US \$8.00
1972	£4.00	US \$8.00
1973	£3.00	US \$6.00
1974	£3.00	US \$6.00
1975	£2.25	US \$5.00
1976	£2.50	US \$5.00

Listing the year's papers by both author and subject, they assist quick, easy reference to past issues.

### BINDERS

Keep your copies of *Nature* protected in durable black PVC binders:

- 20 plastic retention strips mean no loose parts, wire, or complex loading systems
- title blocked in gold on spine
- panel on spine for your own references

Each binder is designed to take two volumes of *Nature*; three binders will serve for a year.

Prices (including postage): UK £3.00 each, three for £8.00; Rest of World US \$6.00, three for US \$16.00.

To order, please send details and correct remittance to:

*Nature*,

Circulation Department,  
Macmillan Journals Limited,  
Brunel Road, Basingstoke,  
Hampshire RG21 2XS, England

Cheques should be made payable to *Nature*. Payment may be made in any currency at the prevailing exchange rate.

Registered No: 785998 England  
Registered Office:  
4 Little Essex Street  
London WC2R 3LF

### MATTERS ARISING

How did barium titanate particulates stick together in the Nebula?	H. H. Schloessin	192
Diversity of deep-sea benthos	M. Williamson	192
Contemporaneity of late Cretaceous extinctions	L. van Valen and R. E. Sloan	193
Do fatty acids inhibit gibberellin-induced amyloysis?	P. Meredith	193
Reply	D. C. Buller and J. S. G. Reid	193
An imbricate thrust model for Southern Uplands of Scotland	E. K. Walton and J. A. Weir	194
Reply	W. S. McKerrow, J. K. Leggett and M. H. Eales	194

### Nature book service

A new service to readers start this week: see pp xii & xiii

## On the move?

You can announce your change of address, free of charge, in a new section in *Nature*—whether the move be permanent or just for a sabbatical period. Send your present and future address, the date of moving and, if applicable, the date of return to On the Move, *Nature*, 4 Little Essex Street, London WC2.

# **The Solution**

## **for *in vitro* lymphocyte isolation**

# **Ficoll-Paque<sup>TM</sup>**

**Ficoll-Paque is a sterile solution of Ficoll 400 and diatrizoate sodium (density  $1.077 \pm 0.001$  g/cc). Available in bottles with a rubber septum closure to facilitate sterile handling and in a convenient pack size ( $6 \times 100$  ml). For further details see our booklet available on request.**

**Guide to authors**

● Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.

● Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.

● Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.

● 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures.

Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the *Système International*. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible;  $\exp(a)$  is preferred to  $e^a$  if 'a' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

(i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth ed. (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unlettered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely.

Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

*Nature's* publishing policy is outlined in 258, 1 (1975) and 264, v, 11 Nov. (1976).

Role of Sendai virus fusion-glycoprotein in target cell susceptibility to cytotoxic T cells	K. Sugamura, K. Shimizu, D. A. Zarling and F. H. Bach	251
Isolation of separate Fc receptors for IgG complexed to antigen and native IgG from a murine leukaemia	S. M. Cooper, Y. Sambray and G. J. Friou	253
Antagonism of antigen-induced contraction of guinea pig and human airways	G. K. Adams, III and L. M. Lichtenstein	255
An octopaminergic neurone modulates neuromuscular transmission in the locust	P. D. Evans and M. O'Shea	257

**Guide to authors**

● Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.

● Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.

● Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.

● 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

**Manuscripts** may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the *Système International*. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible;  $\exp(a)$  is preferred to  $e^a$  if ' $a$ ' is more than one character.

**References** are indicated by superscripts in the text. See any contemporary *Nature* for style, but note: (i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65).

Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

**Artwork** should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unlettered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely.

Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

*Nature's* publishing policy is outlined in 258, 1 (1975) and 264, v, 11 Nov. (1976).

Induction of epidermal transglutaminase by hydrocortisone in chick embryonic skin	A. Obinata and H. Endo	440
Ionophore-mediated calcium influx effects on the post-synaptic muscle fibre membrane	D. I. Devore and W. L. Nastuk	441

## Guide to authors

● Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.

● Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.

● Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.

● 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the *Système International*. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; exp (*a*) is preferred to  $e^a$  if '*a*' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note: (i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unlettered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely.

Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

*Nature's* publishing policy is outlined in 258, 1 (1975) and 264, v, 11 Nov. (1976).

Absence of suppressor cells from rats bearing passively enhanced kidney allografts	J. R. Batchelor, L. Brent and P. J. Kilshaw	522

## INDEXES

The following indexes are still available:

	UK	Rest of World
1971	£4.00	US \$8.00
1972	£4.00	US \$8.00
1973	£3.00	US \$6.00
1974	£3.00	US \$6.00
1975	£2.25	US \$5.00
1976	£2.50	US \$5.00

Listing the year's papers by both author and subject, they assist quick, easy reference to past issues.

## BINDERS

Keep your copies of *Nature* protected in durable black PVC binders:

- 20 plastic retention strips mean no loose parts, wire, or complex loading systems
- title blocked in gold on spine
- panel on spine for your own references

Each binder is designed to take two volumes of *Nature*; three binders will serve for a year.

Prices (including postage): UK £3.00 each, three for £8.00; Rest of World US \$6.00, three for US \$16.00.

To order, please send details and correct remittance to:

*Nature*,

Circulation Department,  
Macmillan Journals Limited,  
Brunel Road, Basingstoke,  
Hampshire RG21 2XS, England

Cheques should be made payable to *Nature*. Payment may be made in any currency at the prevailing exchange rate.

## Nature for Christmas

Why not give a friend or colleague a year's subscription to *Nature* as a Christmas present?

For full details of our special Christmas scheme (which includes an unusual free gift), please circle number 56 on the Reader Enquiry Card in this week's issue, or write to The Promotion Manager, *Nature*, 4 Little Essex Street, London WC2R 3LF.

# Cellulose ion exchangers should be spherical too

## DEAE-Sephacel<sup>®</sup> is

DEAE-Sephacel<sup>®</sup>  
Total capacity: 1.4 meq/g  
Wet diameter: 40–160  $\mu$ m

The spherical form of DEAE-Sephacel gives you easy, uniform packing without the generation of fines. It improves your results because it reduces zone broadening and ensures uniform, high flow rates. DEAE-Sephacel is reproducible from batch-to-batch.

No precycling is needed because DEAE-Sephacel is ready swollen. Its controlled macroporous structure, which is almost completely independent of pH and ionic strength, gives high protein capacities and excellent recoveries.

DEAE-Sephacel is the only spherical cellulose ion exchanger.

ELF emissions observed at Moshiri	M. Hayakawa and Y. Tanaka	703
A vitreous Kr-2SiO <sub>2</sub>	R. Wang	705
Anion deficiency in strontium titanate	M. A. A. Franco and M. Vallet Regi	706

## Guide to authors

● Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.

● Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.

● Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.

● 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the *Système International*. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible;  $\exp(a)$  is preferred to  $e^a$  if 'a' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

(i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unlettered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

*Nature's* publishing policy is outlined in 258, 1 (1975) and 264, v, 11 Nov. (1976).

Climatic information from $^{18}\text{O}/^{16}\text{O}$ analysis of cellulose, lignin and whole wood from tree rings	J. Gray and P. Thompson	708

# How Britain runs its science

This highly successful chart, which appeared in Nature 28 August 1975 (but is still much requested and much referred to), has now been completely revised and updated to include all major changes in the personnel and administration of British science.

Measuring approximately 2' x 3' and containing black-and-white illustrations of prominent figures, copies of this chart are now available at 75p (UK), US \$1.50 (Rest of World).

Payment may be made in any currency at the prevailing exchange rate. Cheques should be made payable to Macmillan Journals Ltd. Prices include postage and packing.

To order please complete the coupon below, or write, enclosing the correct remittance.

3 November 1977

## Sixty years of Soviet science

NEXT WEEK, on 7 November, the Soviet Union celebrates the sixtieth anniversary of the October Revolution. The discrepancy in dates, reflecting the change-over from Julian to Gregorian reckoning, neatly symbolises one of the major results of the Revolution—a commitment to implementing the results of modern scientific progress in the building of socialism.

For forty years, this policy was viewed from abroad as no more than an attempt to catch up with the burgeoning Western industrial economies. Soviet leaders' remarks about 'outstripping' the West were dismissed as mere propaganda—until the bleeps of *Sputnik 1* sent Western scientists running to their Russian primers and added to the information explosion an ever-increasing flood of cover-to-cover translations of Soviet journals.

One well-worn theme of Soviet writers on *naukovedenie* (the science of science) is that Soviet science must inevitably overtake the bourgeois variety, owing to its superior ideological basis. While we cannot support the idea that science, properly speaking, can belong to this or that political system, there does seem to be a distinct sociological phenomenon which may be termed 'Soviet science'—science carried out within and in the service of the Soviet State planning structure. Within this system science, like every other branch of production, is organised into neat five-year planning blocks. Research is envisaged officially as a search for 'solutions' to particular problems of the national economy, with the All-Union Academy of Sciences as 'coordinator for the whole scientific work of the country', and increasingly centralised control and 'unification' of academic institutions.

Unfortunately, it is precisely this centralised control which has led to major set backs for science in the Soviet Union, when high-level intervention by planners or ideologues overrode the scientists' desired research programmes. Lysenkoism, Stalin's attempt to ban quantum mechanics, the slow start in cybernetics (it appeared contrary to certain dicta of Marx and Lenin) are hardly a convincing argument for leaving decision-making in the hands of the State Planning Commission. Nor has this trend ceased. In recent years, the psycho-

logical theories of Snezhnevskii, who would attribute all mental disturbance and social nonconformity to schizophrenia, even when no schizophrenic symptoms are discernible, have begun to acquire the status of official dogma, and seem well on their way to repeating, in psychology, the disastrous course into which Lysenkoism led Soviet biology.

While the days are long past when a student might be asked to comment on the 'class significance' of a differential equation, ideological soundness remains a matter of utmost concern to the Soviet authorities. According to the latest (1976) regulations, a postulant for a higher degree must "combine a profound professional knowledge with a mastery of Marxist-Leninist theory and with the convictions of an active builder of Communist society". Official biographies and obituaries describe a scientist's minor Party offices as meticulously as his academic laurels. Organisers of international conferences know all too well that a Russian scientist of world repute will frequently fail to appear, being replaced by a junior colleague of mediocre scientific ability but greater Party commitment.

No one can deny the considerable achievement in Soviet science and technology over the last six decades, nor the fact that certain achievements, notably major irrigation projects, the space programme or the development of the resources of Siberia, would hardly have been possible without a centralised planning system. In the eyes of the comrade-in-the-street, science and scientists have acquired considerable charisma. Orders and decorations are regularly bestowed on deserving scientists by a grateful government.

Yet, by a typically Russian paradox, the constitutional position of scientists was until now anomalous in a State based officially on the union of workers and peasants. Only in the past month, with the publication of the revised constitution, has this been extended to read "workers, peasants, and intelligentsia". Recognised at last as part of the basis of the State, it is to be hoped that Soviet scientists will receive as an anniversary present a greater measure of freedom of movement and immunity from bureaucratic interference without which no science can effectively flourish. □

# The lipid hypothesis: orthodoxy by default?

John Rivers, a London-based nutritionist, looks at the debate over diet and coronary heart disease

Dr George Mann is a university teacher, a physician, a nutritionist and a heretic. He is one of the small number of outspoken opponents of the theory that the key to the modern epidemic of coronary heart disease (CHD) is the consumption of too much fat which is too high in cholesterol and has too low a ratio of polyunsaturated to saturated fatty acids. That this opposition should justify the term 'heretic' is not a reflection of the unchallengeable nature of the evidence supporting the 'lipid hypothesis', but the extent to which official gatherings of experts in different countries have made it national policy.

CHD is a sudden event, but as it only occurs in arteries narrowed and made less resilient by atherosclerosis, its origin must be sought in the factors which lead to years of deposition of cholesterol-rich atheromatous plaques. Virchow's observation over a century ago that the cholesterol in these plaques is derived from serum cholesterol suggested high serum cholesterol was the primary cause. Ample epidemiological evidence backs this view. The disagreement starts when one seeks the cause of high serum cholesterol.

As over 90% of our body cholesterol is endogenously synthesised, Mann dismisses dietary cholesterol as an important determinant of serum cholesterol. Rather, he suggests, one should look for factors which alter rates of synthesis or excretion. In his view the latter is crucial, and he notes a reduction in cholesterol breakdown is known to result from exposure to high levels of atmospheric carbon monoxide—hence the importance attached to smoking and pollution—and from consumption of *trans* unsaturated fatty acids.

Powerful evidence can be adduced to support his view that present dietary hypotheses of hypercholesterolaemia are mistaken. For example, a recent study of 2,000 subjects in Michigan found no significant differences in intakes of energy, total fat, unsaturated fat, saturated fat, or cholesterol between the upper and lower tertiles for serum cholesterol. What ultimately matters, however, is not the effect of diet on serum cholesterol but its impact upon mortality from CHD. Reviewing the dietary modification trials that have been conducted to date, Mann concludes that differences in mortality in primary or secondary clinical trials have yet to be shown. Although mortality from CHD is reduced in some, a diagnosis of the cause of death is relatively soft data, and the total death rate has remained constant. Mann argues that if CHD mortality really fell in these trials, mortality from something else must have risen for the total deaths to have been constant. He points out that this often seems to be cancer.

The idea that polyunsaturated fats predispose towards cancer dates from the studies of Pearce and Dayton (*Lancet* i, 464–467, 1974). Many nutritionists regard the idea as unproven—at the least the evidence about it is conflicting. But it is Morton's Fork. If, like Heyden (in *The Role of Fats in Human Nutrition*, Academic Press, 1975), one dismisses the apparent rise in cancer deaths as due to poor design of the trials, then the trials are also too poor to provide evidence about deaths from CHD. The trouble, says Mann, is that the experiments are not scientific. Scientists should design experiments to disprove hypotheses—dietary trials are still being done to confirm them. Because the lipid hypothesis is still not proven after 27 years, he says, the time has come for a rethink.

More troubling than Mann's scientific objections to the

lipid hypothesis are the effects that widespread acceptance of it has had. It has become self-sustaining: heretical opponents find it difficult to obtain research funds, and the medical hypothesis is being increasingly used as an advertising ploy—a massive vegetable oil industry needs evidence for the benefits of polyunsaturated fats.

Even more important, though, we may be doing exactly the wrong thing. Pursuit of the lipid hypothesis does not mean just swapping polyunsaturates for saturates. Polyunsaturates are too unstable, so much of the extra polyunsaturated fatty acids are provided by the substitution of soft margarines and stabilised vegetable oils for butter and animal fats. The trouble is, both changes lead to a dramatic increase in consumption of *trans* fatty acids, compounds whose known hypercholesterolaemic effect (Vergossen and Gottenbos, *The Role of Fats in Human Nutrition*) outweighs the putative benefits of polyunsaturated fats.

Butter contains 8% of its fatty acids as *trans* isomers, the product of biohydrogenation in the rumen. Vegetable oils, which like soft margarines are usually partially hydrogenated, contain *trans* fatty acid levels of up to 40%. Manufacturers of polyunsaturated oils and margarines may proudly state that they are high in polyunsaturates, but they do not state the levels of *trans* fatty acids, nor do they feel obliged to point out the crucial modification that those fatty acids may have undergone.

Like many of the critics of the lipid hypothesis, Mann has sought supporting evidence for his view from studies on the Masai. These meat- and milk-eating pastoralists have low serum cholesterol in spite of a high consumption of animal products. Mann argues that this can be expected—they have low levels of environmental pollution and eat little *trans* fatty acid. Nevertheless, his studies on 50 aortae obtained post mortem show that they do get atheroma but its effects are minimised by the tendency of the coronary artery to widen with age. This Mann attributes to heavy exercise, pointing to epidemiological studies which show a protective effect of heavy exercise. The question obtrudes itself. Is a dietary solution being sought because it is more acceptable than exercise?

It was sad that, to hear Mann talk, I had to attend a press gathering organised by the Butter Information Council, a public relations body representing the dairy industries of Europe. One must regret that he was not asked to present his views to a scientific audience, although they do have available a good summary in his latest paper (*New England Journal of Medicine* 297, 644–650, 1977). Our dietetic fate is in danger of being decided by a public relations battle between margarine salesmen and cowherds.

In the face of this, however, we cannot seek reassurance from the deliberations of the expert committees on the topic. Two successive UK committees on heart disease, under the aegis of the Department of Health and Social Security (*Diet and Coronary Heart Disease*, HMSO, 1974), and the Royal College of Physicians (*J. Roy. Coll. Physicians*, 10, 213, 1976), have come to diametrically opposed conclusions about the value of the lipid hypothesis. The evidence available to both was substantially the same. The latest report, from a US Senate Committee under Senator George McGovern, has recommended among other things a reduction by 30% in dietary total fat intake accompanied by a 50% rise in the consumption of polyunsaturated fatty acids. Such sweeping changes are only likely to be achieved by a substantial shift towards the use of vegetable oils and, according to Mann, may cause more problems than they solve. Not all that he says is convincing, but it is a powerful criticism of a view that is in danger of becoming orthodoxy by default. □

# Improving bench work

Recent legislation affecting employment in Sweden has implications for research, as **Wendy Barnaby** explains

**S**HOULD research be regulated by the laws that govern industry, or is research a special kind of activity needing a different set of laws? The question arises in Sweden as a result of legislation over the past couple of years to strengthen the employee's position in relation to the employer, and it has a good number of scientists worried. For although a few very small categories of employees are exempted, the laws apply to all sorts of working places, and these include universities, research institutes as well as factories, bureaucracies and businesses. Given the different needs of these organisations, the question arises whether it is possible to design one set of rules which will secure the employees' place within them and at the same time improve the quality of their output. It is becoming obvious that the answer is no.

The Law on Security of Employment, which came into effect on 1 July 1974, is the one with the most dramatic effects on research. Its basic tenets are that employment is to last until further notice, which cannot be given without reasonable cause. An employee who is dismissed can contest the dismissal in a court of law and is generally entitled to keep his job while the case is being decided. The law thus abolishes the traditional principle that the employer can fire employees as he sees fit. It also contains various rules about the order in which employees are to be laid off in times when there is no work for them to do (a 'last in first out' basis) and specifies that an employee laid off for this reason has first option on new jobs with his old employer for a year after his dismissal.

The Social Democrats' intention in passing this law was to protect lower-paid workers whose jobs were at the mercy of market trends. It is a long way from the conveyor belt at Volvo to university laboratories, yet the law applies to people working at both. In practice, it has meant that university lecturers have gained security in their jobs instead of having to re-apply for them annually or every third year. Only one category is still competitive, that of research assistant (*forskarassistent*), a position filled by a newly-graded PhD who has to re-apply for it after three years. The reasoning behind this exemption, according to a representative of the academics' union at one of Sweden's larger universities, is that possibilities should be kept open for

PhD's who want to go on researching and teaching.

On paper some flexibility has also been maintained with the prestigious position of docent, the last of the stepping stones to professorial rank. A docent's contract lasts for three years, after which time it may or may not be renewed. Because most docents are in their forties and fifties and have probably spent all their working lives at the university, it looked too callous to throw them out on to the street if they had become stale in their research. Under the law, therefore, the university is obliged to create for any docent whose contract is not renewed a new position at equivalent salary but not involving research. The funds for this are to come out of the university's research revenues. It is an extremely expensive way out, so expensive that it is hardly ever resorted to. In practice, docents have tenure.

Thus, after the statutory six months probation period, all members of a university department except research assistants have tenure, with docents' security practically assured. The results are not hard to imagine. No incompetents can be fired, so no new blood (except research assistants) can be hired. There is minimal circulation of staff and, many complain, a loss of creative atmosphere. The Rektor of Uppsala University, Professor Torgny Segerstedt, says there is an enormous risk that research will become very static.

Its effects will be felt in other ways, too. "I don't dare hire a new secretary", says one professor, "because I know I'll never be able to get rid of her if she turns out to be no good." A microbiologist complains: "I have a good research project I'd like to start, and I've even got a grant for it. But I can't hire a laboratory assistant. We could be stuck with him for ever". In theory, the law allows short-term contracts for specialists hired for a particular task, but in practice this may be impossible to enforce because it is difficult to identify a scientific project as a special job being done in an institute concerned with the same area of research. An assistant employed on, say, a two-year project who wants to stay at its completion would probably succeed in proving that he has taken part both in the specialised project and in the general work of the institute, and would then be considered to have been employed by the institute as

All affected:  
lab assistant to glass-blower

such.

Against defenders of the law who say that research council grants will keep some turnover in projects and personnel, it is argued that such grants will become just as tied up as ordinary projects because they are formally given to the universities which then pass them on to the successful applicants. When any project is over, therefore, the researchers could claim that it had been the university, not the Council, that had been employing them, and demand to stay. At this point the university would be obliged to see if it could find the displaced researcher a job he was competent to do, even if he was not enthusiastic about it.

Thus, a research biologist could be offered a job tutoring biology to first-year students, if such a vacancy were available. If no department had any suitable vacancy, the university would be entitled to fire him on the grounds of there being no work for him to do. In practice the university, acting totally within the law, has retained displaced researchers by firing the most-recently employed members of staff in jobs suited to the displaced researchers' qualifications. In small institutes, however, the regular staff normally dependent on research grants have to leave if their grants are not renewed.

It is difficult to see how, under the law, any research project could be abandoned while the researchers wanted to carry on with it. This raises questions about the whole direction of research: how to drop enquiries which are no longer interesting or profitable, and how to swing research into new channels. Problems would arise not so much at the end as at the beginning of new projects. Unless job security for skilled technicians can be provided, they won't be there in the first place.

#### Working life law

The other law making itself felt at research institutes is the Act on the Joint Regulation of Working Life (*Medbestämmandelag*, MBL), which came into force at the beginning of this year. Its purpose is to increase union participation in decision-making. It does this partly through revising the rules about decision-making, so that the management has to inform and negotiate with the union if any major changes are contemplated, and partly through widening the scope of issues about which the union is entitled to have a say. The most important provision in this respect is that unions and management who have a collective agreement on wages and conditions of work—which nearly all have—should negotiate agreements on joint regulation, which will set out the rights of the workers to organise and assign

work, hire and fire employees, and in general carry on the work of the organisation. The management is also required to provide the unions with information about financial and production matters and personnel policy.

Because most research establishments are financed by the government, the effects of MBL on research are somewhat modified by the Public Employment Act (*Lag om Offentlig Anställning*), which is designed to give public employees the benefits of MBL without trespassing on that part of their work which, because of democratic norms, the public at large has the right to preside over. As far as research institutes go, this means that the employees would not, for example, be able to change the general focus of research as laid down by parliament in the institute's statutes. It also means that, although the management must inform and negotiate with the union, it is not obliged to accept union opinions in questions considered to be in the public domain. In the absence of agreements on joint regulation, MBL in research institutes is at the moment largely a matter of an increase of information and negotiation. But the new system does take up a lot of time.

In some institutes, the atmosphere has been poisoned by union-management disagreements over how MBL should work. "Academic unions are young and inexperienced in comparison with industrial unions", says one physics professor who has had a hard time of it. "They minimise the role of informal contacts and consultations which are so important in industrial negotiations". Although running-in problems are giving some of

the unions a bumpy ride, all agree that their power has increased. "Research is expensive", comments one employee, "and if everybody has to take part in all decisions and planning it will cost more money, time and paper. With the help of MBL, employees might insist on comfort in laboratories instead of equipment. On the other hand, MBL based on public opinion might enforce the financing of research which might otherwise not be carried through".

Different disciplines envisage different problems. "Take an experimental team", says another physics professor. "It is made up of, say, a professor, an assistant professor, a PhD, a couple of graduate students and some technicians. It is a small group and its members usually get together and decide on working practices that suit them all, which helps to mobilise creativity and enthusiasm. But the members of these groups are represented by different unions, who are not involved in the immediate situation but who will now decide on what is to happen there. Direct democracy is being substituted by indirect, and it won't help the atmosphere in the laboratories".

Both laws are quite new, and their full impact on research may not be clear for a few years yet. What does seem obvious is that, especially in the case of the Security of Employment Act, it does research little good to be swept up with industry and put into the same legal basket. Some see Swedish research being irreparably damaged. The government is aware of the difficulties and is to conduct a review. In the meantime, Sweden will remain a focus of attention for external as well as internal interests. □

Uppsala University, Scandinavia's oldest

## USA

## Security conscious

*The Worldwatch Institute, the private Washington-based research organisation concerned with global problems, published its latest pamphlet last week. Chris Sherwell reports*

"THE present deficiency of assured energy resources is the single surest threat that the future poses to our security and to that of our allies", the US Secretary of Defense, Harold Brown, told a gathering of business leaders in the United States last week. For a namesake of his at the Worldwatch Institute, the timing was near-perfect. Lester Brown, Worldwatch's president, was about to release *Redefining National Security*, which considers why energy and other global problems pose a new threat to national security that only a new approach can combat.

These new threats to security, Brown says, "arise less from the relationship of nation to nation and more from the relationship of man to nature". From his discussion of them he concludes that the traditional military concept of national security is no longer adequate for an interdependent world facing global ecological and economic problems. Political leaders have to realise that national security is meaningless without global security; countries must address the problem, he says without amplification, "cooperatively".

### OTA appointment

THE position of Director of the Congressional Office of Technology Assessment (OTA) has been given to Dr Russell W. Peterson. He is president of a lobbying organisation concerned with global issues called New Directions and formerly chairman of the Council of Environmental Quality and Governor of the State of Delaware.

The choice follows several months of speculation and political infighting sparked off by allegations that Senator Edward Kennedy was trying to take control of the OTA and had engineered the resignation of its founder and first Director, Emilio Daddario. These allegations were strongly contested at the time and will be further diminished in credibility by the fact that Peterson is a Republican with a reputation for independence. In addition, Kennedy has been scrupulous in avoiding any appearance of interference in the selection process.

Other nominees for the job were Russell Train, former head of the Environmental Protection Agency, Daniel Desimone, presently the deputy director of OTA, and John Sawhill, former head of the Federal Energy Administration.

Sandy Grimwade

The discussion itself ties together several well-known threads of argument that have already appeared in other Worldwatch publications. Thus, in respect of energy, Brown says that an oil-dependent world, in a nuclear limbo and facing climate alteration with heavy use of coal, must act in concert to produce a timetable for a transition to renewable resources. The world's biological systems, on which the global economy depends, says Brown, are similarly threatened by excessive human claims: fishery catches exceed the long-term sustainable yield, tree-cutting exceeds the regenerative capacity of forests, grasslands deteriorate as livestock and human populations increase, and erosion damages croplands as population pressures mount.

Brown takes his arguments further. Humans can inadvertently or intentionally alter global climatic patterns, he states, causing agricultural output to shrink and adversely affecting the survival prospects of hundreds of millions of people. And a "basic transformation" in the world food economy in the 1970s means that the global balance between demand and supply remains delicate. This, says Brown, is attributable to agricultural shortcomings in Eastern Europe and the USSR and agricultural mismanagement elsewhere, rapid population growth and "negative ecological trends"—deforestation, overgrazing, desert encroachment, soil erosion and flooding.

Finally he argues that economic threats to security—simultaneous inflation and unemployment on a global scale—aggravate social divisions, not least through a worsening income distribution. Taken with the other factors, which also translate into economic stresses, the military's role in securing a nation's well-being and survival is "relatively less important than it once was". But political leaders "perceive the new threats dimly".

Outside the optimists who through faith in man's ingenuity see no problems ahead, doubts about all these arguments will come from those who believe ecological and environmental problems will resolve themselves at great human cost regardless of political intervention, and from those who believe in political intervention but have little hope for it. Doubts of the first kind may simply be unacceptable to Brown, but the second kind pose a difficulty. After all, is it really the case that if *all* nations don't hang together they will hang separately? □

## BRITAIN

## Help at the margin

*UK Research Councils have received a small windfall. Chris Sherwell reports*

WHEN the UK Advisory Board for the Research Councils (ABRC) holds its regular meeting at the end of next week, it will consider how to advise Shirley Williams, the Secretary of State for Education and Science, on the allocation of an extra £4 million among the country's research councils. The sum was added to the department's 1978-79 Science Budget by the Chancellor of the Exchequer, Mr Healey, in his 'mini-budget' last week. Science administrators who recognise, in the words of one, that "it is the margins which cause us the misery", greeted the news enthusiastically.

It is not yet known whether the extra cash represents a once-and-for-all increase or the beginning of a longer term upturn. No indication of what precisely will be happening in the period after 1978-79 is yet available. This means that research councils must prepare options: greater expenditure on capital projects or special programmes will make different demands from improved research grants, for example, which would be recurrent. Last year's forward look means that a fair amount was already known of what councils might want to do with the extra cash.

Mrs Williams has asked the ABRC for its "urgent" advice. If a decision is not made next week, the next meeting is set for 9 December. □

## NETHERLANDS

## Limited progress

*The position regarding recombinant DNA research in the Netherlands is still not clear. Casper Schuurings reports*

THE old Dutch government, still in office five months after the 25 May elections, has decided to start preparing legal rules for recombinant DNA research in the Netherlands. The minister of Health and Environmental Protection, in a letter to parliament, says that so long as not enough is known of the positive and negative consequences of this research, no concrete judgment can be given about the contents of such legislation. "There is also not enough known about the social relevance of this research and therefore of the priority it must have in research generally". In the meantime,

he added, the greatest possible reserve should be exercised.

Practising scientists have expressed their disappointment and concern over this lack of clarity about the policy the government foresees. They fear that the degree to which the Netherlands is falling behind in this field will become greater, and there is concern about the matter of contracts between researchers, their universities or institutes and the Commission on Genetic Engineering of the Royal Netherlands Academy of Sciences. The Commission published a report on 30 March which concluded that recombinant DNA research should be developed with stringent precautions and according to clear regulations contained in legislation which should be implemented quickly.

The government is not following this advice exactly, but the signing of research contracts has not ceased. Researchers at the Free University of Amsterdam signed a contract with their own board and with the commission, and the group is about to start work. Safety control remains with the university itself. Groningen University has also signed a contract, but is further from starting.

The commission's report proposed two commissions, one concerned with safety measures, the other with ethical aspects. The minister, however, announced a new and broader *ad hoc* commission to take over a part of the task of the Academy's commission, which is now composed only of experts. This *ad hoc* commission has to register, advise and indicate the potential dangers of the research in different categories of risk.

The League of Scientific Researchers last month reacted critically to the report, saying it "underestimated and played down" the risks of recombinant DNA research. "The safety measures proposed by the commission are suggested more by their feasibility than by their demonstrated safety", the league said, and praised the minister, who will not return in the new cabinet, for perceiving the need for a broad discussion and for a broader commission. The league recommends a "freezing" of the experiments, and urges the government to stimulate discussion involving scientists, politicians, the lay public and others.

No requests have come so far from industry to start recombinant DNA research. Unilever announced earlier that it was making preparations, and Gist-Brocades is known to be doing the same. But union members are unhappy about this. One of the largest unions in the country has written to three ministers requesting a stop to the research while no legislation exists.

## COMECON

● Protests against the US decision to produce neutron bombs have occupied an important place in the Comecon media over the past three months, with special emphasis being placed on protests by scientists or scientific bodies. Not surprisingly, such protests have so far come from the scientific establishment, but more recently even 'dissident' opinion was called in as support, with an interview on Prague radio with Academician Andrei Sakharov in Moscow.

Sakharov's opposition to nuclear warfare is well known. Early in his career of protest he turned over his savings from his work on the Soviet hydrogen bomb to cancer research. It was his apprehension of the danger of nuclear catastrophe which led to his first major *samizdat* essay, *Progress, Coexistence and Intellectual Freedom*, in 1968. As a Nobel Peace prize-winner, Sakharov would surely have been approached even earlier in the current campaign were it not for his reputation of dissidence.

The interviewer attempted to dissociate 'Sakharov the Soviet scientist' from 'Sakharov, the number two Soviet dissident', alleging that in this second *persona* Sakharov merely rubber-stamped the views of his wife—the implication being that while she was in Italy for medical treatment, people could witness the 'real' Sakharov. But he refused to comment on the neutron bomb, save in the context of nuclear armament as a whole. The question of this one particular weapon, he said, must not be misused for propaganda purposes and must not be given moral and emotional overtones. He also suggested that it was fear of a (conventional) Soviet attack on Western Europe which had led the USA to work on the neutron bomb, and that, although convinced that neither the Soviet Union nor any nation wants a war, twice in this century wars had broken out "irrationally".

This latter statement, which contradicts the classical Marxist interpretation of twentieth century history, was characterised by the interviewer as "ludicrous". Sakharov himself was said to bear the "evil marks" of dissident thinking. But in spite of this and Sakharov's refusal to take action against one specific weapon, the interview was broadcast and presented as something of a journalistic scoop for the current anti-neutron bomb campaign.

● *Interkosmos* 17, launched on 24

September, inaugurated a new generation of Comecon space probes. Previous *Interkosmos* craft had been small, relatively light satellites used for limited studies of cosmic and solar radiation, the magnetosphere and ionosphere. The satellites were not properly stabilised with respect to the Sun, and hence the data obtained was only of a fairly general type.

Accordingly, a new type of satellite, called an "automatic general-purpose orbital station" (AGPOS) was developed for the *Interkosmos* programme. A prototype was launched last year as *Interkosmos* 15; *Interkosmos* 17 is the first operational AGPOS. Designed for long-term automatic operation, the AGPOS includes a special orientation system and can even be equipped with an orientation platform to carry instruments for the high-accuracy investigation of solar flares.

Although the *Interkosmos* programme theoretically includes all countries of Comecon, six out of the twelve on-board experiments were provided by Czechoslovakia, including a laser reflector to determine the distance between the satellite and earth, a silicon cosmic-ray detector, and devices to measure the mass and velocity of meteorites. Czechoslovakia is playing an increasingly large role in the *Interkosmos* programme. Czech trainee-cosmonauts preparing for the manned *Interkosmos* programme are reported to have completed their theoretical work and are training in simulated conditions. One of them is expected to go on a mission with a Soviet cosmonaut in 1978.

In addition to participating in *Interkosmos*, Czechoslovakia has also provided experiments for the Soviet *Prognoz* 4, 5 and 6 satellites which have highly elliptical orbits. The launching of an independent Czechoslovak satellite, and the inclusion of Czech instruments on Soviet lunar and interplanetary probes is also envisaged.

At the same time Bulgaria, hitherto a relatively minor participant in *Interkosmos*, is also planning an independent space programme to be associated with the 1,800th anniversary of Bulgarian statehood next year. A recent decree of the Council of Ministers approved a regulation introducing "a nationwide programme to study and utilise outer space, and a preparatory programme to launch into outer space the project 'Bulgaria 1300'".

Vera Rich

## IN BRIEF

**Food action urged**

A publication from Earth Resources Research, the research arm of Friends of the Earth in Britain, urges government action using taxes and subsidies to encourage consumption and production of foods that strengthen consumers' health, minimise environmental pressures and make the best use of food resources.

*Changing Food Habits in the UK*, by Chris Wardle, argues that the two main government regulatory bodies, the Food Standards Committee and the Food Additives and Contaminants Committee, should be provided with their own scientific staff and research facilities. There should also be, he says, an intensive programme of consumer education on nutrition, the introduc-

tion of nutrition labelling, and an independent body to oversee all forms of food advertising.

**German technology assessment?**

The opposition CDU/CSU parties in the West German Bundestag have proposed a motion to set up an office of technology assessment. They proposed this once before, in 1972. The new motion follows years of discussion and calls for the office to be set up within the existing Bundestag administration and for expert knowledge to be gained by placing orders both at home and abroad. It is regarded as important that Federal government offices should call on foreign experts for advice. The Bundestag will deal

with the motion over the next few months.

**Europe compact suggested**

Professor Peter Odell, appointed earlier this month as a part-time consultant to the UK Department of Energy, said this week that the restraint on oil and gas development imposed by the lack of a West European agreement should be overcome by a compact between the exporting and importing countries concerned.

In a joint paper with Dr K. Rosing, his colleague at Erasmus University, at an Institute of Fuel conference, he said that Europe's strategy for oil and gas production is "constrained more by politics and institutions than it is by the likely size of the resource base".

THE EEC's Joint European Torus (JET), which was finally given to the UK's Culham Laboratory last week, is essentially a device to confine the ionised particles of a plasma long enough for fusion reactions to occur between them. The two light elements most suitable for use in fusion machines are deuterium and tritium. The former is plentiful—it can be extracted from seawater—but the latter does not occur naturally and is made by bombarding lithium, a naturally occurring element, with neutrons.

The most successful machine designed so far for confining plasma, the tokamak, was developed in the USSR and forms the basis of the JET design. The plasma is confined within an evacuated D-shaped torus by a magnetic field, created by field coils linking the torus, and by a current flowing through the plasma. For the energy obtained to be greater than that put in, plasma temperatures have to be about 100 million °C and the product of plasma density and confinement time has to be greater than  $10^{14} \text{ cm}^{-3}\text{s}$ .

It is the attainment of such stringent operating conditions that has made fusion so difficult to harness. JET aims to achieve higher temperatures and plasma densities and longer confinement times than any of its predecessors. According to the original plan it was to take five or six years to build. Experiments were then to proceed for two to three years, by which time they would have produced good enough results for a prototype reactor to be designed.

There is doubt, however, about the realism of this timescale. In spite of progress so far, it is unlikely that

the road to what has been called a cheap, inexhaustible and clean source of energy will be smooth. As well as technical problems, those of fuel

**Fusion's promise****BACKGROUND**

supply, waste disposal and potential radiation leaks will have to be tackled, even though these may not be so great as those for fission reactors.

The radiation hazard stems from the possible release of tritium, a radioactive gas which will have to be contained within the reactor. Tritium for the fusion process will be manufactured as hot neutrons interact with lithium in the container walls. Constant bombardment of the walls will make them radioactive and wear them out so that they will have to be replaced from time to time. Even

though the products of the fusion process will not be radioactive and will pose no disposal problem, the old reactor walls will. The fuel supply problem will arise when world reserves of lithium run low. Present estimates put the reserve at about the same as uranium.

The enthusiasm for fusion as the answer to the world energy problem is based on the knowledge of what it could do, theoretically and not on what it actually might do on a large scale. If the fusion reaction were between deuterium and deuterium, for example, the problem of lithium supply would vanish. If it were between deuterium and helium-3 an added advantage would be that neutrons would not be produced and the problem of damaged radioactive walls would vanish. Similar advantages would be gained by using hydrogen and boron. But all these alternative fuels have their drawbacks when it comes to operating a large scale fusion machine, mainly because they would need even higher temperatures to ignite fusion reactions. Deuterium and tritium are at present the only promising fuels.

The outlook for JET itself, however, is fairly bright considering the two years delay. While politicians were negotiating, the team at Culham was building one-off pieces of equipment and refining the design. It has already placed phased contracts for some of the larger parts including the coils for the toroidal field. The next step is to appoint a head of project and management committee. Firm contracts for the rest of the parts will be placed throughout Europe and construction should begin within a few months.

## Petition for Argentinian scientists

SIR,—Some colleagues in our cancer centre are very concerned by the actual situation in Argentina and we have decided to propose the adjoining text for the approval of the international cancer community.

The undersigned cancerologists are very concerned by the situation in Argentina where personal security is increasingly threatened, fundamental rights are denied and where repression and arbitrary police action severely effect the scientific community ('Repression in Argentina: scientists caught up in tide of terrors' *Science* **194**, 1397; 1976; and 'More on Argentina' *Nature* **263**, 452; 1976).

These cancerologists refuse to participate under such conditions in the twelfth International Cancer Congress, which is scheduled for 5–12 October 1978 in Buenos-Aires, and ask all the members of the international scientific and medical community to join them in their refusal.

The undersigned also refuse to participate in meetings organised in any country subject to police repression and where the rights of man are systematically violated.

We invite physicians and scientists who share these opinions to join us in this protest by signing this petition. Copies of the petition will be made available on request to Dr J-C. Salomon, Institut de Recherches Scientifiques sur le Cancer, CNRS, B.P. 8, F 94800 Villejuif, France.

A similar action is underway among United States cancerologists.

LOUISE HAREL

JOSE URIEL

JEAN-CLAUDE SALOMON

Villejuif, France

## Exchange agreement

SIR,—I was glad to see Vera Rich's article (13 October, page 553) about the new exchange arrangement between the Royal Society and the Academy of Sciences of the USSR, but sorry to note that it contained several misleading statements. Firstly, the seven senior and four junior visits she referred to are in the *current* agreement, and are replaced in the new agreement, to come into effect on 1 April 1978, by a more flexible arrangement for a total of 49, not 40, man-months. The Royal Society hopes that this number will be increased and that the more flexible exchange agreement will lead to wider support for visits in both directions.

Vera Rich's comparisons with UK–Poland exchanges are also highly misleading as the figures she quotes for UK–USSR visits refer only to those under the Royal Society–Academy exchange agreement and do not refer to many visits under other auspices, while those for UK–Poland are evidently all-inclusive; Royal Society–Polish Academy visits account for only about ten each way.

R. W. J. KEAY

The Royal Society,  
London, UK

## Which diet?

SIR,—Colin Blythe and Howard Rush in their article 'What kind of food policy?' (4 August, page 386) mention the confusing advice available "to individuals who wish to follow sensible eating regimes".

Over past years ever-increasing doubt has been cast upon the validity of the theory that animal fats and cholesterol in human food cause arteriosclerosis and its resultant disorders. Even drastically reducing fat consumption and substituting animal fats to a large extent with distasteful plant oils of high polyene acid content, does not restore blood cholesterol levels to normal, nor bring about a retrogression of arteriosclerosis.

The fat theory offers us no explanation of the fact that in primitive populations, whose diet contains a very high proportion of animal fats, the incidence of arteriosclerosis and abnormal blood fat levels is practically nil. The diet of such people (Massai, other nomadic tribes, Eskimos) usually contains very little carbohydrate. Might is not therefore be the carbohydrates and not the fats that are responsible for the cardiovascular disorders connected with other types of civilisation?

Support for this idea is provided by observations on the cholesterol levels in

subjects of various age groups on a low-carbohydrate diet (70 g daily). Data collected from over 300 individuals have revealed that the cholesterol can be brought down by 50 mg% in 39% of the patients over 60 years of age, in 52% of those between 40 and 60, and in 67% of the group under 40. In the under-forties, restriction of carbohydrate intake can bring about permanent normalisation of the values within a short period of time, if we consider the average values as shown in the figure.

The possibility exists that every case of hypercholesterinemia could be reversed, or even avoided in the first place, if a low-carbohydrate diet were to be adopted in time. If we were to consume as little carbohydrate as the above mentioned primitive peoples, hyperlipidaemias and arteriosclerosis would probably not occur. Such disorders develop over the years under the influence of unphysiological quantities of carbohydrate (and their reversibility declines with advancing years) until the point is reached at which animal fats and cholesterol in the food bring about a rise in blood cholesterol levels. The efficacy of a low-carbohydrate diet in reducing overweight and in correcting metabolic disorders has already been established. Perhaps it would now be worthwhile considering the substitution of the fat theory by a carbohydrate theory in explaining the diseases connected with human civilisation.

## On missing the point

SIR,—It is surprising that Bowne (13 October, page 556) finds some research ridiculous since it involves the discussion of polygenes, which are "unknown". It is surely a basic part of the scientific method to describe observed phenomena (familial resemblance for metrical characters) in terms of abstract entities (polygenes). Current work in genetics is not analogous to von Leeuwenhoeck studying ribosome structure, since the phenomena accessible to him did not suggest the idea of the ribosome.

## Aether drift detected at last

from Michael Rowan-Robinson

A GROUP of experimenters from Berkeley (Smoot, Gorenstein & Muller, *Phys. Rev. Lett.* **39**, 898), using a U-2 aircraft in the unfamiliar mode of looking upwards, seem to have decisively detected the motion of the Earth with respect to the cosmic microwave background. This radiation, with the spectrum of a 2.7 K blackbody, is believed to be the relic of the 'fireball' (radiation-dominated, optically thick) phase of the Universe. The isotropy of the microwave background to one part in  $10^3$  has been the strongest argument in favour of the homogeneous, isotropic models of the Universe dreamed up by Einstein, de Sitter, Friedmann, Eddington and Lemaître in the 1920s. But it has long been expected that a simple dipole anisotropy of order  $10^{-4}$  to  $10^{-3}$  should be found, due to the random motions that galaxies have with respect to each other and to the cosmological frame of reference (the frame in which the expansion of the Universe looks exactly isotropic, according to the models). The radiation should look slightly hotter in the direction we are travelling towards, and slightly colder in the direction we are travelling from, by an amount  $\Delta T/T \approx v/c$ , due to the Doppler shift. Failure to detect this effect would put us in the uncomfortable position of happening to be exactly at rest with respect to the cosmological frame. It was Michelson and Morley's failure a century ago to detect a contribution from the motion of the Earth to the local velocity of light that led to the downfall of aether theories and ultimately ushered in the relativistic age. A completely isotropic microwave background might have been equally revolutionary, but the Berkeley workers seem to have saved us from this fate. However the magnitude of the velocity deduced for the Milky Way,  $600 \text{ km s}^{-1}$ , is so large as to

throw existing ideas about our cosmic environment into disarray.

The Berkeley group did their experiment in the NASA-Ames Earth Survey U-2 aircraft and made eight flights over a period of 5 months. Two radiometers working at a frequency of 33 GHz ( $\lambda=9 \text{ mm}$ ) point at positions  $60^\circ$  apart on the sky,  $30^\circ$  on either side of the zenith, and the difference between the signals in the two receivers is recorded. An isotropic background would therefore give zero output wherever you looked. The plane flies on a level path, banking and reversing its direction of flight every 20 min. The whole apparatus is rotated through  $180^\circ$  every 64 s in order to eliminate asymmetry between the two radiometers. Anisotropy in the Earth's atmospheric background is monitored with a second receiver working near the strong oxygen line at 5 mm. The effect of any rapid changes in the gain of the radiometers is reduced by rapid switching between them at 100 Hz.

About 5% of the sky was sampled, all in the Northern Hemisphere. The results agreed well with what would be expected due to motion of the Earth: a temperature excess in one direction, a deficit in the opposite direction, and in between a cosine dependence on the angle between the direction of the peak and the direction of observation. The derived velocity, after correction for the motion of the Earth round the Sun and other minor effects, is  $390 \pm 60 \text{ km s}^{-1}$  towards a direction R.A. (Right Ascension)  $= 11.0 \pm 0.5 \text{ h}$ , declination (dec.)  $= 6^\circ \pm 10^\circ$  (galactic longitude ( $l$ )  $= 248^\circ$ ; latitude ( $b$ )  $= 56^\circ$ ). This is within  $2\sigma$  of the recent preliminary ground-based measurements of Corey & Wilkinson (*Bull. Amer. Astr. Soc.* **8**, 351; 1976), which are of lower accuracy. When corrected for the motion of the Solar System round the Galaxy, the net velocity of our Galaxy with respect to the microwave background is  $603 \text{ km s}^{-1}$  in direction R.A.  $= 10.4 \text{ h}$ , dec.  $=$

$-18^\circ$  ( $l=261^\circ$ ,  $b=33^\circ$ ). Apart from this dipole anisotropy the microwave background is isotropic to one part in 3,000 and limits can be set on the rotation of the Universe ( $<10^{-9}$  arc s per century) and on the average energy-density of long-wavelength gravitational radiation (less than the so-called "critical" density which would close the Universe).

What are we to make of this? The authors note that the velocity they have found conflicts with various attempts to measure our velocity with respect to nearby galaxies, but offer no explanation of this. With respect to the Local Group of galaxies, the motion of the Solar System hardly differs from that expected due to our circular motion round the Galaxy. This suggests that the whole Local Group has to be moving along together at this velocity of  $600 \text{ km s}^{-1}$  with respect to the microwave background. And this velocity is more than ten times the residual random motion of galaxies within 20 Mpc about the Hubble flow, so that most nearby galaxies, including the Virgo cluster of galaxies, would seem to have to move along together at this velocity. The Universe may be much more inhomogeneous than we have realised till now, and we may have to be careful about interpreting the expansion time-scale we measure locally as the age of the Universe.

The Berkeley measurement also conflicts with the velocity of the Earth with respect to more distant galaxies (at several hundred Mpc) determined by Rubin *et al.* (*Astr. J.* **81**, 687; 1976). They also found a velocity of about  $600 \text{ km s}^{-1}$ , but in a direction almost at right angles to the velocity with respect to the background. This 'Rubin-Ford effect' may not seem so surprising now. The matter in the Universe may be divided up into quite large 'metaclusters' or 'superclusters' in rapid motion relative to each other and to the cosmological frame.

It is unlikely that this new result will dent the hot big bang picture of the

M. Rowan-Robinson is a lecturer in Applied Mathematics at Queen Mary College, London.

Universe very much but our ideas about our cosmological locality are in for some revision. The Berkeley group have made an important experiment, which is clearly worth repeating. A

good test would be to do a similar series of flights in the southern hemisphere but perhaps U-2's are still not all that welcome outside US airspace. □

## Visualising jumping genes

from T. Cavalier-Smith

DNA molecules are not an inert repository of genetic information, but are frequently chopped, spliced or modified by enzymes. This occurs not only during genetic recombination, but also during replication, repair and sometimes even during nuclear differentiation; for example, extensive chopping of DNA into pieces occurs during macronucleus formation in hypotrich ciliates (Lauth *et al.* *Cell* 7, 67; 1976). Usually these changes leave the linear order of genes unaltered, but sometimes genes may 'jump' from one part of the genome to another. The first evidence for 'jumping genes' (more properly called transposable or translocatable genetic elements) came long ago from Barbara McClintock's studies of controlling elements in maize (*Proc. natn. Acad. Sci. U.S.A.* 36, 344; 1950). The study of the molecular basis of transposability is now possible as a result of the discovery over the past few years of a variety of transposable elements in *Escherichia coli*. The simplest of these are the insertion sequences (IS), short segments of DNA of defined length and sequence which can become inserted into a larger DNA molecule by a recombination process distinct from *E. coli*'s normal recombination system. They were first discovered as a result of the strongly polar mutations they cause when inserted into the *lac* and *gal* operons, but have since been found in other chro-

mosomal locations and on drug resistance (R) plasmids (for reviews see Cohen *Nature* 263, 731; 1976; Kleckner *Cell* 11, 11; 1977).

Electron microscopy of the molecular hybrids formed after denaturation and reannealing of DNA containing insertion sequences showed that there were four distinct sequences: IS1 of about 800 base pairs, and IS2, 3 and 4, each about 1,400 base pairs long. Chow (*J. molec. Biol.* 112, 611; 1977) has now used electron microscopy to throw some light on their distribution in the *E. coli* genome. Her method (much used in the past few years to study palindromes or inverted repeats in eukaryote DNA) was simply to allow the denatured DNA fragments (in length a few per cent of the total genome) to reanneal for such a short time that most of the duplexes formed were formed intramolecularly by a DNA strand folding back on itself. A single DNA strand can pair with itself in this way only if it contains at least two identical sequences that are inverted with respect to each other. If these inverted repeats are adjacent (forming a palindrome) renaturation produces a double-stranded hairpin; if they are separated by a spacer that cannot pair with itself, a double-stranded stem bearing an unpaired loop at one end is formed. Both hairpins and stem-loop structures are found in abundance in rapidly renatured eukaryote 'snap-back' DNA.

In *E. coli* DNA Chow found no hairpins (which confirms earlier work), but various stem-loop structures were

present, indicating that *E. coli* DNA does contain some inverted repeats long enough to be observed in the electron microscope (but only ones where the two sequences are separated by spacers). The duplex stems of the stem-loop structures fall into four discrete size classes, of which one corresponds to IS1 and one to IS2-4 (duplexes shorter than 400 base pairs were discounted as possible artefacts). The loop lengths are more variable but also fall into distinct classes, most being either 22,000 or 27,500 bases long, indicating a regular arrangement of the inverted sequences on the chromosome. By making various assumptions (including the identity of the 800-base-pair sequences with IS1) Chow estimates that there are a minimum of 14 IS1, and 10 IS2-4 (as well as 6 and 12 respectively of the 500-base pair and 1,000-base-pair sequences) in each genome. A similar study by Deonier and Hadley (*Nature* 264, 191; 1976) revealed inverted repeats only in the 1,300-base-pair size range, suggesting that the IS sequence content of *E. coli*'s genome differs from strain to strain.

Some of the antibiotic-resistance genes carried on R plasmids have turned out to be bounded by insertion sequences (often inverted with respect to each other). The complete genetic unit is termed a transposon and can translocate from one plasmid to another and to the bacterial chromosome without the need for a complementary sequence to be present on the host DNA molecule. It is thought that interaction between the two inverted sequences plays an important part in this translocation.

In view of the apparent importance of inverted repeats one wants to be able to identify them easily. If they are longer than about 200 base pairs electron microscopy of the snap-back DNA fraction shows hairpins or loop-stem structures, but shorter inverted repeats do not show up in this way. Much shorter inverted repeats do exist, however, for example bacteriophage Mu DNA contains a segment of DNA (the G segment—3,000 nucleotide pairs long) which is flanked by inverted repeats each of less than 50 nucleotide pairs. In the prophage (but curiously not in the infective state) the G sequence readily inverts, presumably as a result of recombination between the inverted repeats. These short inverted repeats are seen by electron microscopy after denaturation and self-annealing as a 'cross over' of the two strands at a reproducible position (as in the letter α). But in DNA less well characterised than Mu it would be hard to distinguish between such cross overs caused by limited base pairing

T. Cavalier-Smith is a lecturer in the Department of Biophysics, King's College, London.

The four structures visible in the electron microscope after reannealing denatured DNA containing inverted repeats. a, Hairpin; b, stem-loop structure; c, α-structure with defined crossover; d, underwound loop formed by partial pairing of two complementary α-structures.

and the chance lying of one strand on top of another normally seen in the electron microscope.

Detection of such short inverted repeats will be made much easier by the recognition by Broker *et al.* (*J. molec. Biol.* **112**, 579; 1977) that following denaturation and reannealing they give rise to a characteristic structure which they call an 'underwound loop.' When a single molecule containing two short inverted repeats anneals with itself it forms a structure with a single-stranded loop and two single-stranded tails (like an  $\alpha$ ). If the DNA is left to reanneal long enough the loops of separate molecules will come together in complementary pairs. But this pairing must be incomplete. This is because each of the loops in the two interacting molecules is topologically equivalent to a circle (because of the base pairing at the cross-over point), and two circles, unlike two linear strands, are topologically unable to undergo the high degree of winding necessary to make a complete double helix. Some pairing is possible at the expense of twisting and tangling the rest of the molecule; the 'underwound loop' that results therefore contains both double-stranded and single stretches of DNA which are clearly visible in the electron microscope. Broker *et al.* use this method to reveal the short inverted repeats at the ends of the Mu G segment (presumably the G segment is a transposon since an identical sequence is present in phage P1, where it has much longer terminal inverted repeats), those at the ends of adenovirus-2, and at the two ends of the  $\gamma\delta$  segment (a 5,700-base-pair sequence found at the boundary between F (sex factor) DNA and chromosomal DNA).

This technique will be valuable for detecting short inverted repeats separated by a spacer. I suspect that it will not be long before they are reported in eukaryote DNA. The fact that in *E. coli* the G segment can have either short terminal repeats (as in Mu) or long ones (as in P1) suggests that there is no fundamental functional difference between the long inverted repeats that abound in eukaryotes and the short ones which have so far been reported only in bacteria.

So far, ideas as to the function of palindromic sequences in eukaryotes are very vague (see *News and Views* **262**, 255; 1976). One possibility is that they have no function for the organism as a whole; they may even be disadvantageous 'selfish genes' maintained by strong positive selection at the level of the individual gene balanced by negative selection at the level of the organism; this would be entirely consistent with their tendency to trans-

## The Sun and the weather

from Roger H. Olson

OVER the past few years, research into the relationships between solar activity (such as sunspots, flares and sector boundaries) and various climate and weather parameters has become more respectable. Although the search for mechanisms has as yet yielded few results, the number of impressive statistical correlations is steadily increasing. One of the best examples is the work of J. M. Mitchell, senior climatologist with the National Oceanic and Atmospheric Administration (NOAA). Mitchell has been looking at the correlation between sunspot activity and periods of drought in the Western United States, particularly since AD 1700, established from tree ring analysis.

Mitchell has worked with C. W. Stockton and D. M. Meko of the University of Arizona Tree Ring Laboratory, in studying the size of the area covered by drought in the Western United States. First, tree ring patterns, based on several types of trees, over the past 40 years were compared with well-known periods of drought. Once this standard correlation had been established it was possible to trace periods of drought back to AD 1700. A variety of sophisticated techniques were used to compare the period and geographical extent of the drought with the sunspot cycles, which have been observed reasonably consistently back to the beginning of the period.

No evidence was found for any influence of the 11-year cycle, but there is a very strong match between periods of drought and the 22-year double sunspot cycle (the Hale magnetic cycle). The area covered by drought tended to reach a maximum about 3 years after every other minimum in the 11-year cycle, with the most recent well-documented drought being that of the mid-1950s, correlat-

ing with the sunspot minimum of 1954. (The drought of the 1970s seems to be correlating with the sunspot minimum of 1976.)

The time between droughts averaged 20.4 years, whereas the average double sunspot cycle is 22 years. The reason for this apparent discrepancy is that the best coherence between drought area and sunspots comes during times when the sunspot maxima are high. It is during such periods that the time between successive maxima and minima tends to be smaller. When the sunspot numbers are small, the period of the cycle increases, and the correlation with drought area becomes weak.

Another tree ring series, dating back to AD 1600, was made available to Mitchell by H. C. Fritts. Although this series is not amenable to the statistical treatment mentioned earlier, it does contain one additional bit of information worthy of comment. During the Maunder minimum (see *News and Views* **236**, 405; 1977), when sunspots were virtually absent from the Sun during a 70-year period, the drought periodicity persisted in the Western United States. This suggests that the visible sunspot may not be the best parameter of solar activity to be used in the study of Sun-weather relationships.

A lesson to be learnt from Mitchell's work is that different meteorological parameters may behave in dramatically different ways. His study uses the area covered by drought, rather than the amount of rainfall or some other more arbitrary parameter. Rainfall statistics are notoriously hard to work with, because of their variability and dependence on topography. □

Roger H. Olson is at the Aspen Institute for Humanistic Studies, Boulder, Colorado.

locate and cause mutations. A more attractive proposition is that they may be the key to understanding the mechanism of cell determination. An important feature of determination is its great stability, inheritable over many cell generations. Although in principle this is explicable in terms of an association between DNA molecules and controlling proteins (and/or RNA) which is so stable that it can persist during replication and division, I think that the idea of a semi-permanent change in the DNA itself has been unduly neglected. Holliday and Pugh (*Science* **187**, 226; 1975) have put forward a most attractive mechanism involving

methylation of short palindromic sequences. Yet another possibility would be a change in the primary sequence of the DNA mediated by insertion sequences. Such a change would be inherited automatically by daughter cells, but would in principle be perfectly reversible (for example, when the nuclei of differentiated cells are transplanted into oocytes). Such changes could be inversions, deletions, duplications or translocations and could switch genes on and off by creating or destroying the recognition sites for controlling proteins. If the IS-mediated events commonly occurred only during DNA replication and were specifically

inhibited by the incorporation of bromodeoxyuridine into DNA then a jumping gene model could explain in a unifying way all the basic features of cell determination (see Reinert & Holtzer *Cell Cycle and Cell Differentiation*, Springer, 1975), including that in the immune system, as well as the apparent inconstancy in the position of palindromes in eukaryote DNA (Perlman *et al. Cell* 8, 33; 1976). The transformed state in cancer (strongly heritable in somatic cells) could also result from a change in the primary sequence of the DNA concerned with the regulation of proliferation, as a result of stable aberrations in IS-mediated events (either spontaneous or mediated by radiation, chemicals or the insertion of viruses into the DNA).

Now that bromodeoxyuridine has been shown to inhibit bacterial sporulation (*Nature* 267, 635; 1977) it may be possible to test such ideas in more tractable prokaryotic developmental systems. There may well be fewer basic differences between prokaryote and

eukaryote genetics than has hitherto been thought. The presence of long perfect palindromes in eukaryotes in spite of their absence in prokaryotes, for example, need not be a basic difference. It could be explained simply by supposing that IS sequences and transposons are even more important in eukaryotes than in prokaryotes and are so abundant that they are often adjacent; the junction between two adjacent transposons each of which has identical inverted repeats at its termini would be a perfect palindrome. Perfect palindromes would thus be merely the coincidental result of the coexistence in the genome of large numbers of transposons with similar termini.

Although a transposon or jumping gene theory of cell determination has many attractions, the key question about DNA palindromes is: will their study provide a way towards an eventual understanding of cell determination in eukaryotes, or shall we find that they only lead us back to where we started? □

discovered a receptor for adenosine which also activates adenylate cyclase. At this stage it seems that the adenosine and  $\beta$ -adrenergic receptors compete for the same enzyme, activating it through a common GTP-binding coupling unit. The adenosine receptor, however, seems to be coupled permanently to the enzyme. Further study of this system should be very instructive in sorting out the spectrum of receptor-adenylate cyclase interactions, including the possibility raised by P. Cuatrecasas (Wellcome Research Laboratories, Triangle Park) that the receptors reside permanently in separate membrane domains from the enzyme, never coupling but rather acting through molecular messages.

As the biochemists struggle to characterise a few receptors, so the pharmacologists keep increasing the choice for future biochemists. For example,  $\beta$ -adrenergic receptors in the brain as in peripheral tissue can be subdivided into  $\beta_1$  and  $\beta_2$  types (S. Nahorski, University of Leicester) and there seem to be several distinct classes of  $\alpha$ -adrenergic receptor (D. H. Jenkinson, University College, London). Other new evidence on adrenergic receptors came in the Harden lecture delivered by S. H. Snyder (Johns Hopkins University). Both  $\alpha$  and the  $\beta$  receptors in brain, he reported, are sensitive to sodium ions. Physiological concentrations of sodium decrease the binding of agonists but increase the binding of antagonists to the receptors (and the reverse effect can be demonstrated for the angiotensin receptor). That suggests a generalisation of the two-conformation receptor model previously proposed for the opiate receptor by Snyder.

Much pharmacological evidence for multiple opiate receptors (some recently published: *Nature* 267, 577; 1977) was presented by H. Kosterlitz (University of Aberdeen). A new line of evidence comes from a comparison of the action of various opiate agonists in two strains of mice. Although enkephalin was equipotent in the two strains there was a large difference in their response to normorphine.

Most of the interest in the opiate receptor, however, remains firmly focused on the endogenous ligands. D. Smyth (National Institute for Medical Research, London) started with mention of the recently discovered very large '31K' precursor to both ACTH and  $\beta$ -lipotropin, the latter being the precursor of all the endogenous opiates except leucine enkephalin. He then summarised his (and others) evidence demonstrating high opiate-like activity of the peptide (C-fragment or  $\beta$ -endorphin) derived from residues 61 to 91 of  $\beta$ -lipotropin. C. R. Snell, from Smyth's

## Receptors and hormones

by Peter Newmark

The Eleventh Harden Conference was held on 19-23 September, 1977 at Wye College. It was organised by Dr L. Iversen.

WHEN the identity of some receptors is about as substantial as the Emperor's new clothes it is always a real pleasure to hear of the nicotinic acetylcholine receptor. Even so there is still no purified receptor to show for the huge effort that has been made in that direction along a path strewn with discarded subunits.

Everybody finds a major acetylcholine-binding subunit of around 40,000 dalton by SDS electrophoresis but there is considerable dispute about the reality and significance of other, larger subunits. Are they part of the receptor (M. Raftery, California Institute of Technology), experimental artefacts (J. P. Changeux, Pasteur Institute) or simply absent (E. Barnard, Imperial College, London)? Barnard reported one of the first purifications of the acetylcholine receptor from mammalian tissue (denervated cat hind leg muscle) and found it to be remarkably similar to the more thoroughly studied receptors of the electric organs of the electric ray and eel.

A further growing problem in the

purification of the acetylcholine receptor is that of the functional heterogeneity of its subunits: it is not known how the binding of acetylcholine is translated into ionic transport across the membrane. Is this an integral property of the receptor itself or is a separate molecular entity responsible? Substantial evidence in favour of the latter was reported by M. Eldefrawi (University of Maryland) and by Changeux. They call the molecule the Ion Conductance Modulator or the Ionophore respectively.

The holy grail of receptor purification seems to be successful reconstitution of a purified, functional receptor in a synthetic lipid bilayer. Just how elusive that grail is, even for the acetylcholine receptor, was evident from the somewhat unseemly anxiety of all those present to point out the imperfections in all reconstitution data so far published.

Also on the slow but steady path to purification is the  $\beta$ -adrenergic receptor (A. Levitzki, Hebrew University of Jerusalem). At the same time Levitzki's group have accumulated kinetic evidence that the  $\beta$ -adrenergic receptor is not permanently coupled to adenylate cyclase. Instead a 'collision coupling' mechanism is involved in activation of the enzyme following ligand binding. That evidence comes from work on the turkey erythrocyte in which Levitzki has very recently

laboratory, next presented evidence for the existence of extracellular endopeptidases that could degrade  $\beta$ -endorphin to  $\gamma$ - and  $\alpha$ -endorphins and to methionine enkephalin. He also showed that various experimental conditions for the extraction of endogenous brain opiates could favour activation of the degradative endopeptidases. Any suggestion however that such degradation accounted for the isolation of enkephalins rather than larger peptides from the brain was quickly discounted by Kosterlitz who pointed out that enkephalins have been extracted as the major brain opiates in conditions in which  $\beta$ -endorphin is not degraded.

Confirmation of that came from R. Miller (Wellcome Research Laboratories, Triangle Park) who then posed the question of the origin of brain enkephalin. The small amounts of  $\beta$ -lipotropin detected in the brain (Snell) indicate that enkephalin is metabolically derived from precursors synthesised *in situ*. Less likely is that brain enkephalin has its origins in  $\beta$ -endorphin released from the pituitary, especially since Miller showed that hypophysectomy had almost no effect on brain enkephalin content.

What then is the fate (purpose?) of the pituitary endorphin? The discovery of a hand-in-hand secretion of  $\beta$ -endorphin and ACTH into the bloodstream from the pituitary (*Science* 197, 1367; 1977) at least opens the possibility that it plays some part in the physiological response to stress.

Another group of peptide hormones to receive attention was the insulin family. T. Blundell (Birkbeck College, London) explained how it was possible to predict the basic three-dimensional structure of insulin growth factor (previously called non-suppressible insulin-like activity) and relaxin from their recently completed amino acid sequences and knowledge of insulin and proinsulin three-dimensional structure. When the structures are compared with that of insulin it becomes clear why insulin growth factor has insulin-like activity but relaxin has not.

Many of the remaining peptide hormones were encompassed in one grand scheme by L. Kohn (National Institutes of Health, Bethesda) who reviewed his evidence that the glycoprotein hormones are composed of two molecular subunits as is cholera toxin. One subunit is responsible for an initial interaction with a hormone-specific membrane ganglioside on the surface of target cells. As a consequence, the other subunit (characterised by a sequence homology that is present also in oxytocin and vasopressin) can penetrate the membrane, after which adenylate cyclase is activated. Recent evidence favours the

inclusion of tetanus toxin and interferon under the same mechanistic umbrella.

Kohn also reported evidence that one of the glycoprotein hormones, thyrotropin, causes an alteration in electrical potential across the membrane of cultured thyroid cells before stimulating adenylate cyclase (*Proc. natn. Acad. Sci. U.S.A.* 74, 2352; 1977). That led him to speculate that ion flow may be the primary event for all the ligands under his umbrella. Primary events were also the concern of R. Michell (University of Birmingham) who summarised the evidence that favours a crucial role for increased phosphatidylinositol turnover following ligand-receptor interaction in many non-cyclic AMP-dependent systems. Unfortunately the evidence, although substantial, is indirect and badly in need of direct, critical confirmation.

Finally a word in praise of the immunologists. They (M. Raff, University College, London; F. Melchers, Basel Institute for Immunology; H. Wigzell, University of Uppsala) superbly met the challenge of presenting their field to a largely ignorant audience in the space of an evening. □

## Colonisation of a volcano inside a volcano

from Jared M. Diamond

THE regrowth of life on islands sterilised by volcanic explosions has offered biologists 'natural experiments' for studying colonisation. Classics of this type include studies of Krakatau (in Indonesia, exploded in 1883; Docters van Leeuwen *Ann. Jard. Botan. Buitenzorg*, 56-57, 1; 1936; Dammerman, *Verh. K. ned. Akad. Wet. Afd. Natuurk.* II, 44, 1; 1948; Borssum Waalkes, *Ann. Bogorienses*, 4, 5; 1960) and Surtsey (off Iceland, arose from the sea in 1963; Fridriksson, *Surtsey*, Wiley, 1975). From observations of these islands, biologists have sought answers to questions such as: How do species differ in their ability to reach an empty island? Of the arriving species, who survives, and why?

A promising new study, by Eldon Ball (Australian National University), Joe Glucksman (Department of Primary Industry, Papua New Guinea), and Jean-Marie Bassot (CNRS, France) is of Long Island off the coast of New

Guinea. A recent visit adds to information that Ball and his coworkers gathered on five previous visits to Long since 1969 (Bassot & Ball *Papua New Guinea Sci. Soc. Proc.* 23, 26; 1972; Ball & Glucksman *Proc. R. Soc. Lond. B* 190, 421; 1975; Ball & Johnson in *Volcanism in Australia*, 133-147 (ed. R. W. Johnson), Elsevier, 1976; Ball *Australian Nat. Hist.* 19, 12; 1977). Factors making Long especially interesting are that its tropical location exposes it to a rich pool of colonists, that it is not just a single island but a nested set all of which have been at least partially defaunated in the past 300 years, that Ball's teams are virtually the only humans to have reached the innermost island (reducing the risk of species introductions by humans), and that there have been multiple colonisation episodes of this inner island associated with successive eruptions.

Long Island lies in the Bismarck Sea 30 miles northeast of New Guinea. It is a forested island of 170 square miles, in the centre of which is a crater lake (Lake Wisdom) of 37 square miles, in the centre of which is a small active volcano (Motmot Island) of about 10 acres, in the centre of which was (from 1968 to 1973) a small crater lake of about 1 acre. By a combination of biological, geological, historical and anthropological detective work, Ball has amassed evidence that an 18th-century explosion buried Long's former biota under tens of metres of lava. Lake Wisdom probably dates from that explosion, at least in its present form. The inner island, Motmot, is the tip of a submerged cone that erupted to form an island in 1943, was twice eroded down to the lake level and recreated by eruptions, and has existed continuously since 1968.

The outer island, Long itself, is already covered with rainforest. Its tree species are ones whose seeds arrived either by floating in the sea (for example *Terminalia catappa*, *Barringtonia* sp.), or else in the guts of birds (*Ficus*, *Canarium*, and *Eugenia* species, probably brought by fruit pigeons). In these forests now live nearly a full quota of bird species predicted for an island of Long's area (except for a deficit of montane bird species), as well as lizards (including the large *Varanus indicus*), snakes, bats, and the arboreal marsupial *Phalanger orientalis* (probably introduced by the humans who recolonised Long in the 19th century).

Lake Wisdom is remarkable for its depth of 1,200 foot, and for having high oxygen concentrations and aerobic invertebrate life down to the bottom. Most other large lakes in this region have anoxic bottoms lacking a bottom fauna. Two factors that may transport

Jared M. Diamond is Professor of Physiology at University of California Medical School, Los Angeles.

oxygen to the bottom of Lake Wisdom are wind circulation and convection currents caused by heating of the water around Motmot volcano. Although the lake's surface is at an elevation of 620 foot and the bottom is thus well below sea level, the water is nevertheless fresh down to the bottom, implying that the lake basin is sealed.

Lake Wisdom's biota is impoverished, compared with that of an older 'control' lake nearby (Lake Dakataua), probably because the lake is little more than two centuries old. The most striking absences are of vascular aquatic plants, copepods, fish, and turtles. However, there are many species of benthic algae, invertebrates (aquatic insects, molluscs, crustaceans, and one species of sponge), and one species each of nesting duck and grebe. Winds and birds probably brought the plants and invertebrates. But the lake also contains at least one adult crocodile. Crocodiles periodically reach the sea-coast of Long in floating rafts of vegetation from New Guinea. How they got several miles inland and up and over the steep crater rim into the lake remains a mystery.

The inner island, Motmot, is difficult of human access because of the steep crater rim, lack of human population on Lake Wisdom's shore, the four miles' distance over the wind-tossed lake from the shore, crocodiles in the lake, and near-boiling water temperatures on some sides. Ball and his co-workers have variously reached Motmot from the lake shore by native-built outrigger canoe, collapsible aluminium boat, dinghy, or swimming while pushing a raft and avoiding the areas of near-boiling water. On Ball's first visit in 1969, 1 year after recreation of Motmot by an eruption, the sole mature plant was a sedge, the sole land invertebrate a lycosid spider. Over the next 4 years the number of plant and invertebrate species respectively increased to 17 and 20, until a new eruption in 1973 destroyed the inner crater lake and wiped out most plants except a sedge. Ducks and swallows nest on Motmot, migrant shorebirds from the northern hemisphere periodically visit, and a falcon visits from Long itself to devour its prey of small birds.

How do the plant and invertebrate colonists reach Motmot? Some arrive wind-blown by aerial rafting. Many are washed up on Motmot's beach, having floated from Long across Lake Wisdom by themselves or on floating logs. Ball found five species of invertebrates on a log that had floated past Motmot. Numerous seeds that wash onto the beach sprout but fail to survive the combination of heavy wave erosion and changing water levels. Some seeds come attached to the feathers and feet of the

nesting ducks and grow mainly in the areas that the ducks frequent. Still other seeds arrive in the guts of the falcon's bird prey.

What invertebrates colonise Motmot, where do they live, and what do they eat? On the beach are beetles, earwigs, ants, and bugs, living off washed-up organic material. Under an algal crust on the inner crater lake are collembolans and rove beetles. Around this lake are ants, scavenging or eating smaller insects. It was a surprise to find a lycosid spider as the earliest land colonist, since they are strict carnivores and since scavengers dominated the early colonists of Krakatau and Surtsey (but a spider was the first organism found on Krakatau after it exploded). What would a solitary carnivore eat? Probably aerial plankton; but lycosids can gorge themselves and survive half-a-year without food.

As yet, virtually no attention has been paid to comparing the species composition of Long's flora and insect fauna with the source biota of New Guinea and New Britain. This would be a rich data base for understanding who does and does not colonise. It could also suggest how much time is necessary for genetic divergence and subspecies formation. For example, the description of an endemic bird subspecies from Long (Salomonsen *Breviora Mus. Comp. Zool. Harvard*, no. 254; 1966) suggests formation of a bird subspecies within two centuries. □

## Tibetan meteorology

from T. B. Tang

IN its working conference held in June, the Academia Sinica confirmed that weather and long-term climatic forecasting has been selected as a key research topic in China; in the same month, its Institute of Atmospheric Physics launched a new journal—*Atmospheric Science*—devoted principally to climatic research. (From the second issue onwards this journal is available and has a table of contents in English). Meteorologically, the Chinghai-Tibet Plateau in western China is of immediate relevance, if only because of its vastness (one-fourth of China's land area). The Plateau has immense dynamic effects on the atmospheric circulation in the Northern Hemisphere and constitutes an important influence on the weather and climate of areas eastward as far as the Japanese Islands.

Recently, there has been much

scientific activity in Tibet. For instance, exploiting the high altitude, the Chinese have set up there an observational station for cosmic rays. Hard on the heels of the completion of field work for the comprehensive geological and biological survey (see *News and Views* 269, 12; 1977), the first major meteorological programme commenced in July this year and, after three months, has now come to a close (*Hsinhua News*, 10 October).

The research programme dealt with weather patterns on the Plateau in the summer, and was carried out collectively by personnel of the Central Meteorological Bureau, of provincial bureaux in northwest and southwest China and the Army, as well as by local meteorologists.

The work included the study of meteorological data collected between 1969 and 1976, the analysis of cloud photographs taken by satellites in recent years, and field surveys along the middle reaches of Yalu-tsaupo River. The detailed findings are not yet available. However, the general picture obtained is that in summer, a high pressure air mass forms in the upper level of the atmosphere; when it moves eastward, it causes drought in the other parts of China. At low levels in the atmosphere there also frequently occur low-pressure eddies and shear lines. These are the weather systems responsible for precipitation in summer on the plateau, bringing damaging heavy rain. In certain circumstances they move eastward and cause devastating floods in southwest, central, and eastern inland China. An understanding of the formation, evolution, and distribution of these eddies and shear lines, as well as their directions of movement and seasonal variations, and the relationship between these factors and precipitation is, therefore, vitally important to weather forecasting and the mitigation of natural calamities.

In the present connection it is of interest to note a review article discussing climatic changes in the Plateau for the past 500 years, which appeared in the September 1977 issue of the popular science journal *Ke Xue Shi Yan*. The article reported that an

### Correction

In the article 'Carbon fixation pathways' (*News and Views* 269, 201; 1977) paragraph 5, line 7 and following should read "Measurements of leaves of quantum yield for CO<sub>2</sub> uptake show the following. At normal oxygen tension and 30 °C, C<sub>3</sub> and C<sub>4</sub> plants show similar efficiencies, but as CO<sub>2</sub> tension increases the efficiency of C<sub>3</sub> metabolism increases whereas C<sub>4</sub> remains constant."

T. B. Tang is at St John's College, Cambridge.

annual mean temperature profile has been worked out, using evidence from the analysis of the annual growth rings of trees; samples were selected from trees found at around 4,300 m above sea level. On the other hand, trees growing at about 3,000 m on forest edges, where moisture rather than warmth becomes growth-limiting were used for estimating annual precipitation. In spite of greater variations from place to place, the picture has emerged that in the 1770s, the 1830s and the early 20th century, annual precipitation was on the whole higher than that at present. It was lower, however, during the longer periods of the late 18th century, the second half of the 19th century, and the mid-20th century. In the past 20 years rainfall has been steadily decreasing by a relatively large total amplitude of approximately 10%. It has been possible to check this picture independently with the observed history of water levels in lakes (from field surveys or satellite pictures), the motion of glaciers (especially their regression), the movements of snow-lines as well as water table levels, and in a few cases with documented records. In general, the results are all consistent with the proposed former variations in annual mean temperature and precipitation. □

## Singlet oxygen in chemistry and biology

from R. B. Cundall

An International Conference on Singlet Oxygen and Related Species in Chemistry and Biology was held on 21–26 August, 1977 at the Whiteshell Nuclear Research Establishment in Pinawa, Manitoba. Many of the papers will be published in a special issue of *Photochemistry and Photobiology*.

THE Earth has an atmosphere containing diatomic triplet oxygen ( $^3\Sigma_g^-$ ); essential for life in the form in which we know it. Consequently an understanding of the chemistry of all oxidation processes which have both beneficial and harmful effects is one of the major problems confronting both biochemists and chemists. The meeting aimed to foster the interaction of physical chemistry with biology in elucidating oxidative transformations, and attracted scientists from fields as diverse as medicine and molecular physics.

A feature of oxygen chemistry is

the interconvertibility of reactive oxidising transients. Attention was mainly directed to the behaviour of  $^1\Delta_g\text{O}_2$ ,  $^1\Sigma_g^+\text{O}_2$ ,  $\cdot\text{OH}$ ,  $\cdot\text{O}_2^-/\text{HO}_2\cdot$ ,  $\text{O}_3$ ,  $\text{H}_2\text{O}_2$ , organic peroxides and hydroperoxides, and derived species such as some of the oxidising inorganic radical anions. Different groups of specialists, showing common interests in oxidation mechanisms presented new work using a wide range of techniques. Particularly prominent were laser photolysis, pulse radiolysis, luminescence, chemiluminescence, ESR, NMR, as well as conventional biochemical techniques, steady state photolysis and radiolysis with product analysis.

Quantitative measurements, mainly by pulse radiolysis, show hydroxyl radicals to be very reactive and to interact unselectively with most biological molecules at rates which are practically diffusion controlled. The fate of the secondary radicals formed by attack on substrates was very much a subject for discussion since it is clear that oxidation in biochemical systems must generate a species of reactivity comparable to OH. The process usually cited to explain this has been

a component of the now classical Haber–Weiss mechanism (1934). This cannot be the reaction involved since it has been established as slow (B. H. J. Bielski, Brookhaven National Laboratory; G. Czapski, Hebrew University, Jerusalem). Alternatives proposed were metal-mediated processes, enzyme-metal catalysis or involvement of peroxides, particularly those derived from lipids.

The low reactivity of the  $\cdot\text{O}_2^-/\text{HO}_2\cdot$  system is now widely agreed and it is clear that in general  $\cdot\text{O}_2^-$ , like  $\text{H}_2\text{O}_2$ , reacts only with such readily reducible molecules as those containing labile SH groups. Nevertheless the biochemical role and significance of the superoxide anion is puzzling. The xanthine oxidase enzyme system is an efficient  $\text{O}_2^-$  generator. The superoxide dismutase (SOD) whose function was first defined by one of the participants, I. Fridovich (Duke University, North Carolina), apparently exists solely to bring about

The nature of this type of enzyme and its properties was a dominant topic in both presentations and discussion. The pulse radiolysis technique has been particularly successful in elucidating the mechanism of these metallo-enzymes (E. M. Fielden, Institute of Cancer Research, Sutton, Surrey). The

use of catalase to remove  $\text{H}_2\text{O}_2$  completes an enzyme trio used to a large extent in mechanistic studies.

Radiation chemistry now has an established role as the most prolific source of information on free radical reactions in aqueous solution and several papers gave evidence of progress in the area. A significant contribution to radiobiology was the demonstration that SOD is an effective radioprotector exerting a protective role even when administered after radiation doses have been delivered (A. Petkau, Whiteshell Nuclear Research Establishment). This clearly shows where knowledge of primary radiation effects and oxidative enzyme reactions can be combined to advantage.

The role of  $^1\text{O}_2$  in biochemical systems is not yet clear. It does not seem to be formed in significant yields from  $\text{O}_2^-$ , in polar systems at least, although it can be formed by chemical reactions which generate it directly or by energy transfer to  $^3\Sigma_g^-\text{O}_2$  from a product formed in the triplet state. The paper of J. Cadet (Centre d'Etudes Nucleaire de Grenoble) in which methodical attempts to generate separately  $^1\Delta_g\text{O}_2$  as well as OH and  $\text{O}_2^-$  and then examine their reaction with DNA constituents shows how the subject is likely to progress in the immediate future.

The use of dye photosensitisers in research on the so-called photodynamic effect is an area in which an important role for  $^1\Delta_g\text{O}_2$  is beyond dispute. The complications arising in particular cases from the simultaneous participation of the Type I (free radical) and Type II ( $^1\Delta_g$ ) processes were described by several authors and the behaviour related to dye and binding properties (T. Ito, University of Tokyo). A number of papers dealt with experimental techniques, especially interesting were those on the use of dye lasers for excitation of singlet oxygen.

Many interesting studies on specific systems were reported; for example M. Kasha (Florida State University) has found that pressurisation by oxygen produces complexes which remain even when the pressure is reduced. The  $^3\text{E}_{1u}$  state of benzene has been revealed and the  $\text{T}_1 \rightarrow \text{S}_0$  emission from pyridine seen for the first time by this method.

An experiment in conference organisation was a public meeting held on the first evening in which five speakers gave short presentations of interest relevant to the content of the scientific programme to a wide audience. Topics were skin sensitivity to light (M. M. Mathews-Roth, Harvard Medical School), free radicals and ageing (J. D. Crapo, Duke University, North Carolina), sunlight and air pollution (B. D. Goldstein, New York University), the ozone layer (H. R. Rawls,

R. B. Cundall is Professor in the Department of Chemistry and Applied Chemistry at the University of Salford.

Louisiana State University), and the fate of spilled oil (R. A. Larson, Stroud Water Research Centre, Avondale, Pa.). More than 300 people from a small community attended and there was active questioning and discussion. This might be a possible way for scientists to bring their scientific work and opinions directly, rather than through the media, to a lay audience, especially on controversial topics. □

## Thin film technology

from C. W. Pitt

The first of an intended series of international conferences on ion-assisted thin film coating techniques was held in Edinburgh on 8–10 June 1977. The Proceedings are available from CEP Consultants, Edinburgh. The next IPAT conference will be held in London in July 1979.

THE presentations covered a wide range of the experimental and production processes, ranging from ion plating, ionised clusterbeam technology, r.f. sputtering, magnetron sputtering, sputter-ion plating, ion implantation and activated reactive evaporation and plasma deposition. An equally large range of applications of the various methods was presented including tribology, tool coatings, corrosion resistant turbine and airframe components, decorative finishes, gas storage, semiconductor, optical and solar devices, electronic components and steel hardening.

A number of the papers were of particular interest to electrical and electronic engineers and solid-state physicists. The paper by T. Takagi *et al.* (Kyoto University) on ionised cluster-beam technology suggested that the required incoming material mobility on the substrate can be achieved by partially ionising clusters of atoms from an adiabatic expansion source and, provided that the deposition rate is maintained at least  $10^3$  higher than the residual gas impingement rate, single crystal and near bulk density films of a wide range of materials may be deposited. The technique has been applied in numerous ways—for example, epitaxial silicon on silicon, InSb on sapphire, GaAs on Cr: GaAs. Silicon solar cells grown n on p, have been fabricated with exposed-surface-layers of 140 Å and which exhibit 70% of the peak output voltage from 450 nm to 950 nm. Low resistance noble metal films deposited on glass substrates have

demonstrated near bulk resistivity in films 200 Å thick; thicker films of the same metals have been used as interconnections on passivated semiconductor chips and have successfully covered 8 µm oxide steps. Furthermore, ohmic contacts have been made to semiconducting material (Ag on n-type silicon, AuBe on p-type GaP) without interface metals or sintering. Ionised cluster-beam deposition on Mn-doped ZnS was also reported to have produced d.c. electroluminescent displays of similar properties to those produced by evaporation and subsequent implantation of the dopant. The superior adhesion properties of the process were demonstrated by the fabrication of flexible printed circuit board which meets the requirements of IPC-FC-240B specification.

K. Jones *et al.* (ICI, Runcorn) have also examined Au, Cu, and Al layers deposited on several types of flexible plastic substrates—polyethersulphone, polypropylene, polyimide and polyester. They concluded that the Cu: polyethersulphone system was particularly suited for flexible pcb construction by the ion-plating process. Ion plating produced good decorative finishes for most of the metal/plastic combination. Sims, in a review of ion-plating applications, again mentioned the fabrication of printed circuit board material. He also cited a number of less obvious applications such as battery-grid coatings which result in an improvement in the energy storage efficiency of lead/acid cells, aluminium coatings for steel and plastic lamp-reflectors and which are subsequently protected by ion-plated glassy layers, and also coatings for X-ray anodes for use in the soft wavelength spectrum. B. Heinz (Leybold Heraeus, Hanau) reported the use of electron-beam ion plating for forming the contact layers of noble metals on reed-relay blades. He and his colleagues have found that the switching lifetime of the plated blades could be enhanced by a factor of 10 times in appropriate conditions, and that the process produced blades with reduced sticking probability and contact resistance. The process is in industrial production.

Anti-reflective and protective coatings for germanium lenses for infrared imaging were discussed by E. Henderson (Pilkington, St Asaph). Although the experiments reported were in the early stages, it was clear that serious consideration is being given to the use of ion plating for depositing ZnS anti-reflection coatings on five-element large-area zoom lenses for operation at 8–12 µm in corrosive atmospheric conditions, in aircraft (for example). Preliminary data indicate an improvement in lifetime of four to eight times in

adverse conditions. C. W. Pitt (University College, London) reviewed the r.f. sputtering process, with particular emphasis on the capability of this process for depositing dielectric films with good optical properties. The technique has been found to be attractive for fabricating optical waveguiding components for integrated-optics applications. Hard graphitic carbon deposits may be prepared by vapour deposition from a hydrocarbon gas excited into a plasma-phase by an r.f. field S. M. Ojha (University of Sussex) presented some details of this process and of the films produced—it was projected that the rather impressive hardness (unscratched by tungsten carbide) and chemical passivity (insoluble in any of the solvents and acids used, including hydrofluoric acid) might lead to applications in semiconductor passivation and infrared filters.

The increasing use of nuclear power stations for generating electricity has produced several contentious issues, not least of which is the disposal of radioactive wastes. The storage of active gases is particularly sensitive in view of the rapid dispersal if the container is damaged. D. S. Whitmell *et al.* (UK Atomic Energy Authority) have devised an ingenious method of containing radioactive <sup>85</sup>Krypton for the required 100–200 yr and which greatly reduces the potential danger if the container is damaged. The gas is incorporated into a copper thin film matrix by plating a thin film of the metal on a substrate by d.c. sputtering, followed by a reversal of the field so that gas ions are bombarded at the deposited film, penetrate and are trapped. The process is then repeated many times until a thick deposited layer with occluded gas entrapment is built up. It was claimed that up to 5% (atomic) gas occlusion could be achieved—a similar storage capability to a high pressure gas cylinder (approximately 170 l of gas at NTP per l of metal). Damage to the deposit results in very little gas release and only from the area local to the damage.

Two papers on ion implantation, by C. Dearnley *et al.* (Atomic Energy Research Establishment, Harwell) and by V. Ashworth *et al.* (University of Manchester Institute of Science and Technology) suggest that semiconductor devices are not the only area in which the electronic/electrical industry will be influenced by this process. The papers primarily dealt with ion implantation of dopants into metals as a means of altering the wear-resistance of the host metal. But it was apparent from the results of tests on the electrochemical potentials of the doped materials that cathodic protection with improved efficiency may well be feasible. □

## Biochemistry of the bacterial catabolism of aromatic compounds in anaerobic environments

W. Charles Evans\*

*Methods of aerobic degradation of aromatic compounds in the biosphere are well understood, but it is only relatively recently that it has been shown how some bacteria can also degrade these substrates in the absence of molecular oxygen. This occurs by photometabolism (*Athiorhodaceae*), nitrate respiration (*Pseudomonas* and *Moraxella* sp.) and methanogenic fermentation (a consortium) in which the benzene nucleus is first reduced and then cleaved by hydrolysis to yield aliphatic acids for cell growth. These methods may be used by microbial communities to catabolise man-made pollutants.*

THE biogeochemical cycles which operate on Earth are essential for the maintenance and continuation of life as we know it. Solar radiation provides the energy which is harnessed by photosynthesis. Relatively simple inorganic chemicals (supplied by soil minerals, natural waters and air) are utilised by autotrophs for their biochemical processes; these feed the heterotrophs. After death, the constituents of living organisms are mineralised again by microorganisms. This dynamic sequence of events illustrated by the biological carbon cycle (Fig. 1) has evolved over a geological time scale and in a variety of physical conditions.

Although there is diversity and increased biochemical complexity as we pass from bacteria to plants and animals, their cellular metabolism and the structures concerned with the basic reactions of life have much in common. Yet, their biosynthetic and degradative powers differ markedly. Plants are unique in making large quantities of insoluble polymers, including the aromatic macromolecules—lignins and tannins—which only microorganisms can degrade. This sector of the C cycle shown in Fig. 2 has the slowest turnover rate of all natural products<sup>1</sup>; soil humus, however, confers beneficial properties on this medium for plant growth.

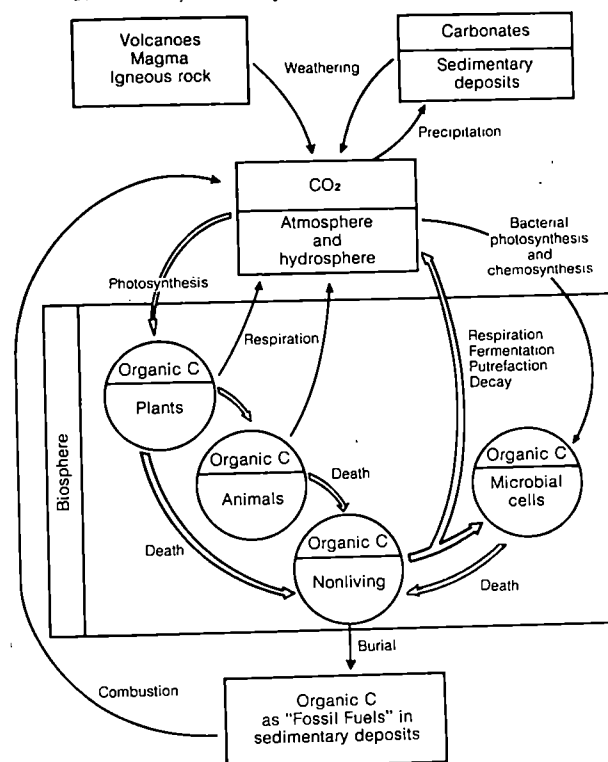

Microorganisms have evolved enzymes of impressive versatility to metabolise natural products; use is made of these in the food industries, water purification and sewage treatment. Science is also applied to control other sectors of the biological C cycle, for example, artificial fertilisers, herbicides, fungicides and insecticides to increase food production; detergents and pharmaceuticals for health reasons. Many of these are synthetic, xenobiotic, aromatic organic chemicals and together with the ever increasing waste products of industry, present an added burden for the mixed microbial populations of soils and natural waters to dissimilate.

Three general methods exist for the catabolism of organic compounds. (1) In aerobic respiration, the oxidation stages occur at the expense of molecular oxygen as the terminal electron acceptor;  $O_2$  is also a reactant for oxygenase enzymes since it is incorporated into the products. The availability of  $O_2$  is often a limiting factor in mineralisation. (2) In anaerobic respiration, bacteria use inorganic electron acceptors to metabolise substrates in the absence of air. Thus,  $NO_3^-$  is reduced to  $N_2$  or  $NH_3$ ;  $SO_4^{2-}$  to  $S^{2-}$ ; and  $CO_2$  to methane ( $CH_4$ ). Although pathways of degradation are usually identical in aerobic and anaerobic respiration, this is not the case for aromatic compounds. (3) In

fermentation, no external electron acceptor is required, the carbon source is degraded anaerobically by a series of reactions that release energy by substrate-level phosphorylation. There is a wide range of fermentation products; aerobic processes are necessary to complete that part of the carbon cycle initiated this way.

Clearly, the utilisation of any of these pathways is determined by the nature of the habitat. Aerobic and anaerobic environments exist in the biosphere; if the oceans are taken into consideration, the size of the latter far exceeds that of the former<sup>2</sup>. Conditions must also be such as to sustain microbial life—nutrients must be available and the pH and temperature favourable—for mineralisation to occur. Vast quantities of organic matter was seques-

Fig. 1 The biological carbon cycle. (Modified from original in *Introduction to Bacteria and their Ecology*, by R. N. Doetsch & T. M. Cook, University Park Press, Baltimore, 1973).

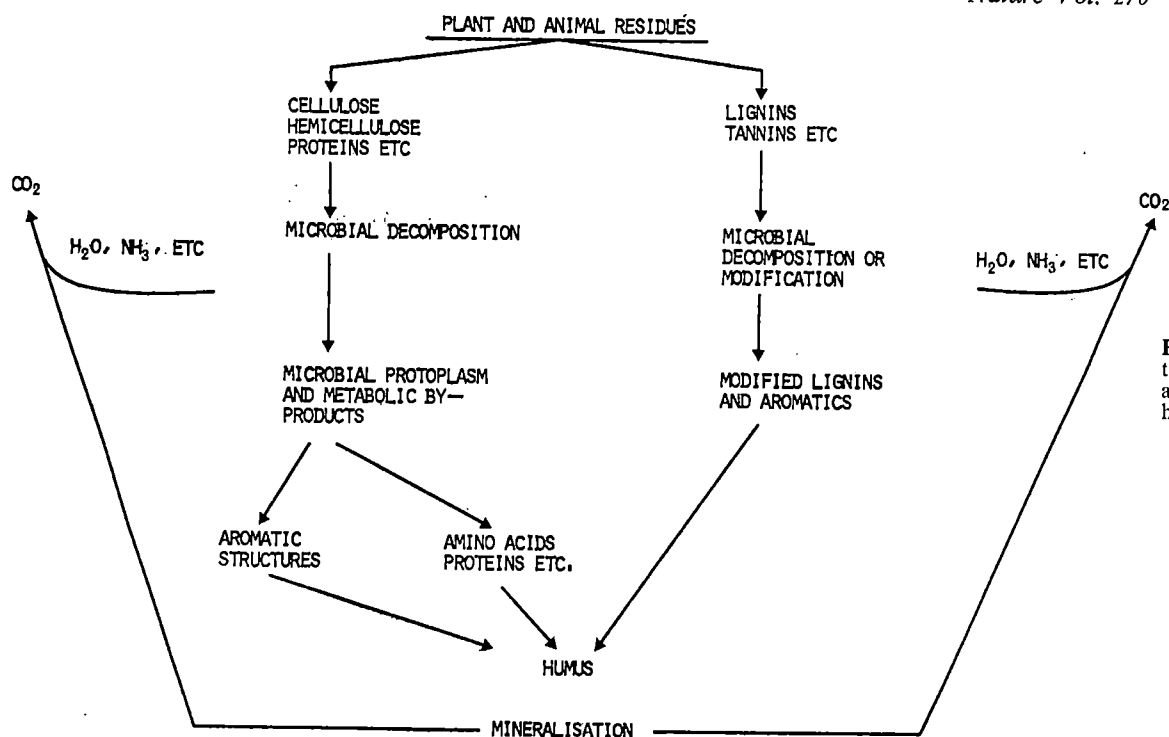

Fig. 2 Organic matter decomposition and formation of humic substances in soils.

trated in the lithosphere in ancient times—now forming the coal, oil and natural gas measures—which remained virtually intact until man began to bring these sources of carbon and energy into circulation again. Soils and sediments provide all the conditions mentioned above; the continuous alternation between aerobic and anaerobic habitats control the biological carbon, nitrogen, sulphur and other cycles in soils<sup>3</sup>.

These factors are well illustrated when we consider the various methods of microbial degradation of aromatic compounds in nature; they also have a basic relevance to the problems of environmental pollution.

### Catabolism of aromatic compounds

It is about 30 years since the salient chemical features of the aerobic *ortho* (intradiol) pathway of bacterial aromatic-ring metabolism was elucidated<sup>4-8</sup>. This was followed by the discovery of the alternative *meta* (extradiol) method by which some bacteria cleave the benzene nucleus<sup>9-12</sup>. These aerobic pathways are initiated by microbial mono- and di-oxygenases; molecular oxygen is essential for them to function since it is incorporated into the reaction-products<sup>13</sup>. They have been extensively reviewed<sup>14-16</sup> and need no repetition here.

Natural selection among microorganisms has explored the chemical possibilities of how to convert stable aromatic structures into useful metabolites; all aerobes employ the device of oxygenative ring-cleavage. In anaerobic conditions this is prohibited; evolutionary considerations indicate that the only remaining options available to bacteria in the primitive biosphere with its anoxic atmosphere are either hydration or hydrogenation followed by non-oxidative ring fission. Chemical considerations indicate that for additions to an aromatic nucleus to occur, the system of bonding characterised by extensive delocalisation of the  $\pi$  electrons must be converted into one in which little of the delocalisation energy remains. Hydrogen saturates the aromatic ring under moderate conditions, whereas addition of water is not observed and is thermodynamically improbable. Predictions made on chemical reactivity alone are not necessarily valid for enzyme-catalysed reactions; indeed, both ideas were at one time entertained. It has now been established that in all cases investigated where aromatic substrates are degraded under anaerobic conditions, the microorganisms utilise the remarkable biochemical device of initial ring reduction, first announced by Dutton and Evans<sup>17</sup>.

Indications that anaerobic methods of aromatic-ring met-

abolism exist in nature which permit cleavage without the participation of oxygen *per se* was provided by Tarvin and Buswell<sup>18</sup>. They reported that benzoate, phenylacetate, phenylpropionate and cinnamate were completely utilised with the production of CO<sub>2</sub> and methane by a sewage-sludge inoculum in strictly anaerobic conditions. During the past decade advances have been made in understanding the biochemistry of this phenomenon. It transpires that the anaerobic dissimilation of the benzene nucleus occurs in at least three different sets of biological conditions and it is the main purpose of this article to delineate progress made in each case.

### Anaerobic photometabolism of benzoate by the Athiorhodaceae

Several species of the purple non-sulphur bacteria, the *Rhodospirillaceae* are able to grow at the expense of simple aromatic compounds as sole carbon source both anaerobically in the light by photosynthetic means and aerobically in the dark by respiration. Proctor and Scher<sup>19</sup>, studying the photometabolism of benzoate by *Rhodopseudomonas palustris*, assumed that the 'bound oxygen' produced by the light reaction (van Niel<sup>20</sup>) was equivalent to molecular oxygen; a pathway similar to the known aerobic methods of dissimilation was therefore suggested. Leadbetter and Hawk<sup>21</sup>, and Dutton and Evans<sup>22</sup>, however, obtained results which made this hypothesis untenable; *Rhodopseudomonas palustris* cells grown photosynthetically on benzoate or the hydroxybenzoates showed no respiratory activity with these substrates in aerobic conditions. Furthermore, such cells were devoid of the enzymes of the aerobic pathways, and the familiar intermediates were not detectable in culture. Figure 3 illustrates dramatically the inhibitory effect of oxygen and the obligatory requirement for light in the photometabolism of benzoate.

It became apparent that another method of biochemical attack on the benzene nucleus must occur in these conditions; the addition of hydrogen seemed to us a distinct possibility. Unlabelled 'test' intermediates to be expected if a reductive pathway operated, were incubated with cell suspensions of *Rhodopseudomonas palustris* actively photometabolising (U-<sup>14</sup>C) benzoate (I); after appropriate time intervals the test compounds were extracted and examined for any isotope exchange. Cyclohexanecarboxylate (II), cyclohex-1-enecarboxylate (III), 2-hydroxycyclohexanecarboxylate (IV), 2-oxocyclohexanecarboxylate (V), and pimelate (VI) became labelled—indicating that the seven carbon atoms of benzoate remain together until after the

Fig. 3 The effects of air, light and darkness on the photometabolism of Benzoate by *Rhodopseudomonas palustris* cells. The initial conditions were anaerobic with illumination. In the period (A-B) between the arrows the conditions were: air-light (○), air-dark (●) and anaerobic-dark (□).

ring cleavage stage. These results suggested<sup>17,23</sup> a series of reactions involving the reduction of benzoate (or a derivative) to a cyclohexanecarboxylate moiety followed by a coenzyme-A mediated  $\beta$ -oxidation sequence. Because the reduced acid is alicyclic, instead of the usual release of acetyl-CoA, breakage of the bond in the 1,2 position occurs to yield pimelate (or its equivalent). This new reductive pathway illustrated in Fig. 4 subsequently received independent support from Guyer and Hegeman<sup>24</sup> who showed that the behaviour of *Rhodopseudomonas palustris* mutants was consistent with such a scheme. We have recently demonstrated the occurrence of these reactions using sub-cellular fractions from *Rhodopseudomonas palustris* grown photosynthetically on benzoate with the following results (ref. 25 and D. O. Lunt and W.C.E., unpublished). (I) A washed chromatophore suspension reduced benzoylphosphate but not benzoate or benzoyl-CoA; light and anaerobic conditions were essential for this to occur. A cell-free extract in the presence of CoA, ATP,  $\text{NAD}^+$  and  $\text{Mg}^{2+}$  ions converted cyclohex-1-enecarboxylate to pimelate in anaerobic

or aerobic conditions and in the light or dark.

These results provide strong evidence for the presence of a light-dependent membrane bound proton-translocating redox system in these chromatophores; the low potential reductant may be a ferredoxin, which also plays a part in photosynthetic electron transport. In addition, they confirm the presence of the appropriate  $\beta$ -oxidation suite of enzymes in these cells responsible for the subsequent series of reactions resulting in ring-cleavage.

Although all members of the *Athiorhodaceae* examined utilise several aromatic acids photosynthetically, some can also metabolise phloroglucinol in these conditions. Using *Rhodopseudomonas gelatinosa*, we detected dihydrophloroglucinol and 2-oxo-4-hydroxyadipate in photosynthetic cultures growing on phloroglucinol as sole carbon source<sup>25</sup>. Surprisingly, a soluble extract from these cells reduced phloroglucinol to dihydrophloroglucinol in the presence of NADPH as specific hydrogen donor in the dark. Our knowledge of the subsequent events leading to ring-fission is at present fragmentary, but is tentatively formulated as in Fig. 5.

### Anaerobic metabolism of benzoate through 'nitrate respiration'

Oshima<sup>26</sup> described a bacterial culture containing two different organisms from soil, which in combination but not separately, grew anaerobically on a variety of aromatic substrates in the obligatory presence of nitrate. Using  $\text{N}^{18}\text{O}_3^-$  and *p*-hydroxybenzoate or protocatechuate as substrate, these organisms incorporated more of the heavy oxygen isotope than with succinate as the C source. He concluded that in the anaerobic cleavage of the aromatic ring, the oxygen atoms of  $\text{NO}_3^-$  were used in a manner similar to that of molecular oxygen. This definitive inference seems unwarranted, bearing in mind the nature of his experiments. Taylor and his collaborators<sup>27,28</sup> then isolated from soil a pure culture of a *Pseudomonas* strain (PN 1) with a similar nitrate-dependent anaerobic metabolism of aromatic acids. Their results showed quite clearly that the anaerobic breakdown of the aromatic ring is different and quite distinct from the aerobic pathways. Although unsuccessful in revealing the pathway, they suggested that aromaticity was destroyed by the addition of three molecules of water to the benzene nucleus in preparation for ring

Fig. 4 Reaction sequences in the anaerobic metabolism of benzoate. a, Photometabolism (*Rhodopseudomonas palustris*). b, Nitrate respiration (*Moraxella* sp.). Methanogenic fermentation by a consortium is initiated by facultative Gram-negative bacteria which perform the reductive and ring-cleavage stages; the resulting aliphatic acids give rise to acetate, hydrogen and  $\text{CO}_2$ , substrates for the methane bacteria (see Fig. 7).

Fig. 5 Anaerobic metabolism of phenol by *Rhodopseudomonas gelatinosa*.

cleavage. (A similar mechanism had been suggested for the aerobic catabolism of aromatic substrates<sup>29</sup>.) We could not agree with their hypothesis on theoretical grounds, yet these workers had drawn attention to an important phenomenon. We also isolated a Gram-negative bacterium from soil which metabolised benzoate anaerobically in the presence of nitrate<sup>30,31</sup>; it turned out to be a *Moraxella* sp. (N.C.I.B.11086) instead of a *Pseudomonas*. Concomitant with the disappearance of the aromatic substrate in these *Moraxella* cultures, nitrate was reduced to nitrogen gas. When (ring-<sup>14</sup>C) benzoate was incubated anaerobically with these cells in nitrate-phosphate buffer, we identified labelled cyclohexanecarboxylate (II), cyclohex-1-enecarboxylate (III), 2-hydroxycyclohexanecarboxylate (IV) and adipate (XII). Using (carboxy-<sup>14</sup>C) benzoate in a similar experiment, the above intermediates were again radioactive with the exception of adipate. Subsequently, we were able to show that *Pseudomonas* PN1 (obtained through the courtesy of Dr Taylor) behaved similarly:

These results imply that the reductive pathway operates in the anaerobic catabolism of aromatic substrates through nitrate respiration<sup>31</sup>. The production of adipate, instead of pimelate in these cultures is explained by a divergence at the 2-oxocyclohexanecarboxylate stage, with its decarboxylation to cyclohexanone (VII) followed by alicyclic ring-cleavage by an unknown mechanism, as shown in Fig. 4.

Recently, Bakker<sup>32</sup> has demonstrated that a mixed bacterial culture adapted from a primary inoculum consisting of a mixture of soil, manure and sewage-sludge, degrades phenol in anaerobic conditions in a nitrate-mineral salts medium. The qualitative composition of this consortium remained fairly constant on serial transfer in liquid culture and consisted of Gram-negative bacteria and a spirillum. It also utilised benzoate, the monohydroxybenzoates, protocatechuate and the cresols in similar conditions. (ring-<sup>14</sup>C) Phenol was converted into <sup>14</sup>CO<sub>2</sub> and radioactive cell material; labelled *n*-caproate and acetate were also identified in the culture fluid. Bakker has, therefore, suggested that phenol is reduced to cyclohexanone followed by a hydrolytic scission of the alicyclic ring to *n*-caproate which can then undergo  $\beta$ -oxidation to give utilisable metabolites for cell growth, represented in Fig. 5. Methane was not produced in Bakker's cultures, presumably because of the presence of nitrate; Chmielowski and coworkers<sup>33</sup>, however, have described a methanogenic fermentation of phenol.

A probable interpretation of events in the bacterial catabolism of aromatic compounds through anaerobic nitrate respiration may be: the reductive phase is accomplished by a ferredoxin-type reductant followed by the  $\beta$ -oxidation sequence and ring-cleavage to aliphatic acids; since these have to serve as carbon and energy source, a part must be oxidised and the resulting reduced coenzymes re-oxidised via a membrane bound proton-translocating redox system which is coupled by the electron transport chain to nitrate through nitrate reductase.

### Methanogenic fermentation by a consortium

The formation of methane and CO<sub>2</sub> from aromatic natural products was the first observation to be made involving the biological destruction of benzenoid structures in strictly anaerobic conditions<sup>18</sup>. It can occur in the absence of nitrate, sulphate

and light through the action of an adapted microbial community. It is surmised that this phenomenon occurs widely in nature, in the processing of sewage and other waste effluents and in transformations of some pesticides.

Clark and Fina<sup>34</sup>, Fina and Fiskin<sup>35</sup> and Roberts<sup>36</sup> working with benzoate as substrate and a consortium adapted from rumen-liquor and/or sewage-digester sludge, applied quantitative radiotracer techniques with the following results: (carboxy-<sup>14</sup>C) benzoate behaved like exogenous <sup>14</sup>CO<sub>2</sub> in that it was not primarily reduced to methane. (Ring-<sup>14</sup>C,1)benzoate appeared mainly as <sup>14</sup>CH<sub>4</sub>; (ring-<sup>14</sup>C,4) benzoate was converted largely to <sup>14</sup>CO<sub>2</sub>. Propionate, acetate and formate were detected in the steam volatile fatty acid fraction of the fermentation liquor. The propionate was labelled in the carboxyl-C when (ring-<sup>14</sup>C,4) benzoate was used (L. R. Fina, personal communication), but not when (ring-<sup>14</sup>C,1) or (carboxy-<sup>14</sup>C) benzoates were substrates.

That the composition of the fermentation gases agrees with the stoichiometry demanded by the equation below was confirmed by Nottingham and Hungate<sup>37</sup> using (ring-<sup>14</sup>C) benzoate:

Although several workers had shown that benzoate-methanogenic cultures utilised certain members of the reductive pathway without a lag period, definitive chemical evidence for their participation was lacking until an abstract of the work of Keith<sup>38</sup> appeared. Isotopic trapping experiments enabled him to identify cyclohexanecarboxylate, cyclohex-1-enecarboxylate, heptanoate, valerate, butyrate, propionate and acetate in such cultures. He proposed that benzoate is reduced step-wise to cyclohexanecarboxylate followed by a reductive cleavage of the C<sub>1</sub>-C<sub>2</sub> bond to give heptanoate;  $\beta$ -oxidation would then degrade this to valerate and propionate with the ultimate formation of acetate, one of the substrates for methane bacteria. Balba and Evans<sup>39</sup>, using similar techniques, also detected the formation of cyclohexanecarboxylate, cyclohex-1-enecarboxylate, propionate and acetate from benzoate in both rumen and sewage-sludge methanogenic cultures; adipate was also identified in the latter fermentation liquor. Although there were about five other unidentified labelled acidic components present, none of these corresponded to heptanoate, *n*-caproate, valerate or butyrate. Prins (personal communication) and his collaborators have identified *trans* 2-hydroxycyclohexanecarboxylate, 2-oxocyclohexanecarboxylate, pimelate, caproate, butyrate, acetate and molecular hydrogen as metabolites of benzoate in methanogenic cultures adapted from the black mud of a polluted river.

Whether the methanogenic fermentation of benzoate is accomplished entirely by species of methane bacteria or if it requires the cooperation of other members of the consortium, remained an open question until recently. In an elegant study, Ferry and Wolfe<sup>40</sup> observed that *o*-chlorobenzoate inhibited benzoate degradation without affecting the production of methane from acetate; the uncoupling of these two steps argues in favour of a microbial food chain. Quantitative studies on the rate of ap-

Fig. 6 Anaerobic metabolism of phenol through *n*-caproate by a consortium in the presence of nitrate. Initial reduction accomplished by an unidentified hydrogen donor (redox potential -0.42 V).

pearance and disappearance of intermediates and formation of products using  $^{14}\text{C}$  labelling where necessary, enabled these workers to propose the following steps in the overall conversion of benzoate to methane:

A careful study of their consortium which had been subcultured for a few years revealed three predominant methanogenic organisms. *Methanobacterium formicum* and *Methanospirillum hungatei* were obtained from the floc in pure culture, but the acetate-degrading methanogenic bacterium defied attempts at isolation. None of these utilised benzoate. A facultative Gram-negative organism which utilised benzoate aerobically was also present, but it failed to grow on this substrate anaerobically even in the presence of nitrate. Their cultures produced methane without a lag-period from cyclohexanecarboxylate, 2-hydroxy-cyclohexanecarboxylate, salicylate, pimelate and acetate; cyclohex-1-enecarboxylate did not behave this way. Ferry and Wolfe<sup>41</sup> point out that the energetics of benzoate degradation make it obligatory for the methane bacteria to utilise the acetate produced if the facultative benzoate-degrader is to obtain energy for growth in conditions which exist in the culture.

In the methanogenic cultures of Balba and Evans<sup>39</sup>, electron microscopy revealed methanogenic bacteria similar in morphology to those already described by Ferry and Wolfe<sup>40</sup>. The facultative Gram-negative organism present in our consortium grew aerobically on *p*-hydroxybenzoate but not on benzoate. It was, nevertheless, able to degrade benzoate anaerobically in the presence of nitrate (compare Williams and Evans<sup>31</sup>). Our cultures continued to produce a gas mixture of approximate composition,  $\text{CH}_4$  (54%),  $\text{CO}_2$  (46%) without a lag-period when benzoate was replaced by alicyclic intermediates of the reductive pathway, the hydroxybenzoates, phloroglucinol, cinnamate, phenylalanine and even shikimate or quinate.

It has now been established that in all these mixed cultures which ferment aromatic compounds to methane and  $\text{CO}_2$ , the benzene nucleus is first reduced and then cleaved to aliphatic acids by facultative Gram-negative organisms; these acids are then

converted to suitable substrates for various methane bacteria to complete the process. The electrons generated are probably excreted as  $\text{H}_2$  gas which is used for the reduction of  $\text{CO}_2$  to  $\text{CH}_4$ . Pure cultures of all the necessary bacteria from these consortia are not yet available for the deliberate reconstitution of the community. It is unlikely that the consortia studied by different workers are absolutely identical in bacterial species composition, yet almost all investigators find the same alicyclic intermediates. The fatty acid anomaly, the occurrence of heptanoate in Keith's benzoate-methanogenic cultures could have other explanations for its origin rather than the one postulated, the reductive cleavage of cyclohexanecarboxylate, a reaction for which there is no biochemical precedent, Fig. 7 shows these intermediates.

Inocula from anaerobic environments where methane gas formation occurs, can be adapted to the methanogenic fermentation of benzoate in about 1–2 months; an initial addition of acetate as well to the culture shortens this period considerably. This does not mean that the benzene nucleus is actually degraded in all these anaerobic environments, for example, benzoate and the aromatic amino acids do not give rise to methane in the rumen; they are excreted as urinary hippurate and other conjugates. Shikimate and quinate are, however, reduced by rumen microflora to cyclohexanecarboxylate which appears in the urine of herbivores as hexahydrohippurate<sup>41</sup>.

The rate-limiting steps in the biological degradation of natural aromatic polymers occur at the stage when it is necessary to dismember the lignins and tannins into their small molecule aromatic components. (Artificial treatment of ligno-cellulosic material with alkali at an elevated temperature results in a much improved utilisation of their phenolic components by methanogenic fermentation<sup>42</sup>.) Extracellular microbial enzymes slowly achieve this aerobically, although there is a paucity of precise biochemical information about these reactions for obvious reasons<sup>43,44</sup>. The catechin tannins present an additional obstacle, because of their tanning properties.

It is difficult, at present, to assess the relative importance of the aerobic and anaerobic methods of decomposition of aromatic compounds in the biosphere. Regarding the latter, the *Athiorhodaceae* require light and anaerobiosis for it to be possible; such habitats exist in oceans and lakes<sup>45</sup>. Soils afford anaerobic conditions frequently generated by impeded drainage or flooding (natural or deliberate); soil aggregates (crumb structure) are anaerobic internally—where the appropriate bacteria reduce  $\text{NO}_3^-$  and  $\text{SO}_4^{2-}$ . Whether  $\text{SO}_4^{2-}$  can also act as a terminal electron acceptor for anaerobic catabolism of aromatic substrates has not

Fig. 7 Probable pathways in the fermentation of benzoate and phenol by adapted bacterial consortia from a variety of methanogenic ecosystems. 1-Methylcyclohexanone is a hypothetical intermediate, but is one of a few possible precursors of heptanoate; others involve reduction of C.2 after a cleavage, or a biosynthetic origin.

R 396

yet been convincingly demonstrated<sup>46</sup>; attempts in the authors' laboratory using *Desulphovibrio* were unsuccessful. Microbial communities in habitats where methane formation occurs abound in nature; they can also be made to produce the gas from a variety of aromatic substrates in the laboratory. Dutton and Evans<sup>47</sup> found that appreciable concentrations of fatty acids inhibited the photometabolism of benzoate—a temporary phenomenon, attributed at the time to competition for coenzyme A. In natural anaerobic environments, cellulose fermentation takes precedence over the degradation of aromatics.

Many factors are concerned in the degradation of organic compounds, irrespective of whether they are of natural or synthetic origin. They are all exposed to physico-chemical forces and biological agents capable of causing chemical change in the biosphere<sup>48</sup>. Dilution processes and time eventually ensure that conditions are created for these factors to operate. Concentrations of noxious chemicals may, however, accidentally reach levels in local areas which are extremely hazardous to life; these require exceptional decontamination measures and legislation. Although many useful pesticides are developed empirically, their mode of action usually depends on a selective interference with some fundamental cellular process. Their structures, apart from certain uncommon substituents (for example, halogen) also frequently bear some resemblance to key biochemicals concerned in metabolism. Some linkages may, therefore, be amenable to attack by constitutive group-specific microbial enzymes. It is a common observation that many of these foreign chemicals are degraded more rapidly by a mixed adapted community of soil microorganisms than by any of the freshly isolated individual members of the group—for example many chlorinated hydrocarbon pesticides under suitable biologically-active anaerobic conditions<sup>49,50,51</sup>; Dalapon<sup>52</sup> (2, 2-Dichloropropionate) and Asulam (M. Khan and W.C.E., unpublished) [Methyl-(4-aminobenzenesulphonyl)carbamate] under aerobic conditions.

A microbial community reacts to the presence of xenobiotic organic chemicals in subtle ways, depending on their structures and the environment; several biological devices are brought into play which ultimately cause their disappearance. Among the known stratagems used are: co-metabolism<sup>53</sup>, enzyme induction<sup>54</sup>, transfer of metabolic plasmids<sup>55,56</sup>, mutation leading to the evolution of enzymes with new specificities and activities<sup>57,58</sup> and microbial interactions<sup>59</sup> as yet imperfectly understood but operating in the methanogenic consortia which anaerobically degrade aromatic substrates.

# Multichannel seismic reflection profiles of the continental crust beneath the Newfoundland Ridge

A. C. Grant

Geological Survey of Canada, Bedford Institute of Oceanography, Dartmouth, Nova Scotia, Canada

*Multichannel seismic reflection profiles extending south from the Grand Banks indicate that large 'basement' features underlying the Newfoundland Ridge are composed of sedimentary strata. The Newfoundland Ridge, therefore, is interpreted as an area of subsided continental crust rather than a ridge of oceanic crust. The J magnetic anomaly intersects this complex, and the physiographic ridge associated with this anomaly may also be continental in origin.*

HYPOTHETICAL reconstructions of the North Atlantic before Mesozoic-Cainozoic seafloor spreading define the south-western edge of the Grand Banks structural block as a transform margin that developed when the African plate was displaced from that region<sup>1,2</sup>. The Newfoundland Ridge (Fig. 1) has been interpreted as the trace of a fracture zone in oceanic crust marking the continuation of this transform margin<sup>3,4</sup>. The Newfoundland Ridge is a physiographic feature that extends about 900 km south-east from the southern tip of the Grand Banks, with a subsidiary projection, the 'Spur' ridge or 'J-anomaly' ridge, extending to the

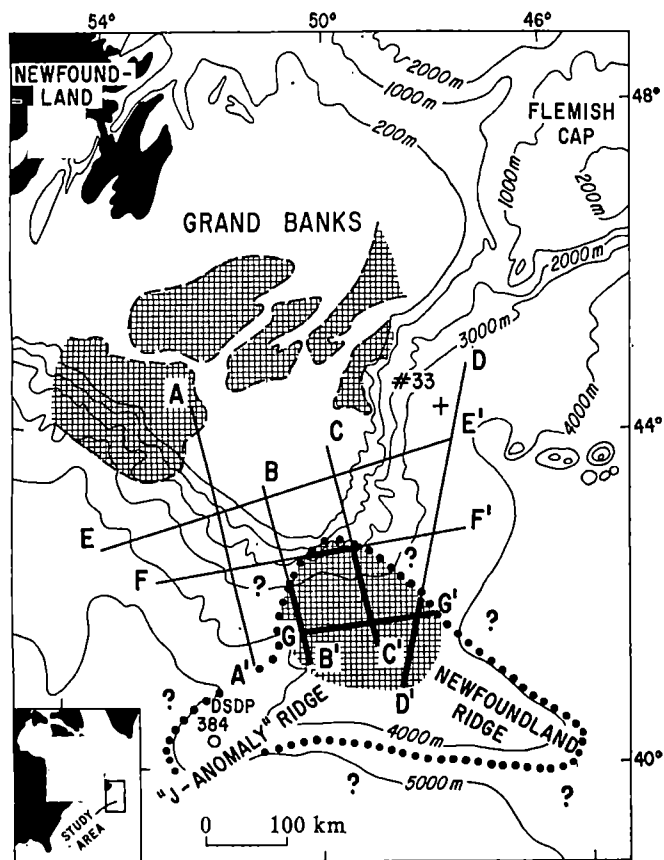

Fig. 1 Bathymetric map of the Grand Banks region (contours in metres). Lettered lines show the locations of the profiles drawn in Fig. 2. The heavy parts of these lines and surrounding crosshatch denote areas where seismic reflectors are apparent beneath event U. The dotted line indicates the minimum extent of sedimentary strata beneath the Newfoundland Ridge inferred on the basis of physiography. Question marks denote the possibility of founded sialic crust adjacent. Cross-hatched areas enclosed by dashed lines indicate the extent of sub-unconformity basins of the Grand Banks. The circle and cross indicate DSDP Site 384 (ref. 11) and sonobuoy station No. 33 (ref. 10).

south-west. Watson and Johnson<sup>5</sup> interpreted seismic profiles from the Newfoundland Ridge as showing buried basement blocks, which had been uplifted and distorted by faulting. From the magnetic anomalies associated with these blocks they inferred a volcanic origin. Ballard *et al.*<sup>6</sup> have described topographic and structural features characteristically associated with the high amplitude (500–1,000 nT) J-magnetic anomaly. Hall<sup>7</sup> and Keen *et al.*<sup>8</sup> have suggested that the J-magnetic anomaly continues north-eastwards with slight offset, across the Newfoundland Ridge. These investigations generally imply an oceanic origin for the Newfoundland Ridge. This paper presents an interpretation of multichannel (24) common depth point reflection seismic data that supports an alternative, continental origin for this feature. These seismic data (Fig. 1) are part of a nonproprietary survey by Seiscan Delta Ltd that the Canadian Government has purchased for the purpose of regional control. Figure 2 shows reduced tracings of reflectors on the processed record sections. The vertical scale magnification of the bottom profile in these diagrams is about 6 to 1. Magnetic data (also from Seiscan Delta) are plotted as anomaly profiles with several of the seismic sections. Figure 3 is a reproduction of a portion of a seismic record section on the Newfoundland Ridge.

### Interpretation of data

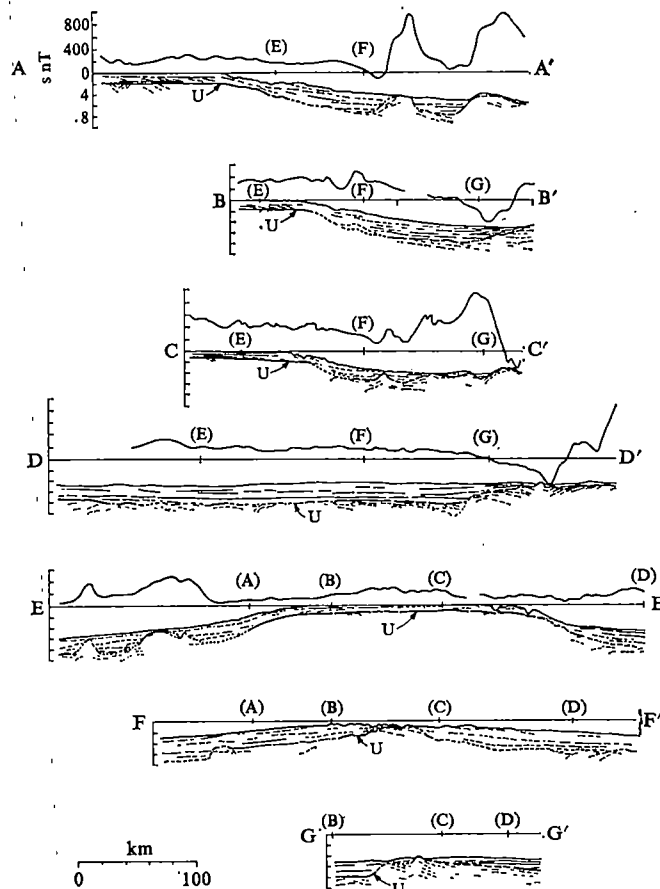

The subsurface geology of the Grand Banks has been outlined through geophysical surveys and exploratory drilling for petroleum<sup>1,9</sup>. A principal element of Grand Banks geology is a late

early Cretaceous unconformity, which separates a blanket of Cretaceous and Tertiary sediments from older rocks in sub-unconformity basins and intervening areas of basement (Fig. 1). This unconformity is an excellent seismic boundary. On the profiles in Fig. 2 the seismic reflections from the unconformity—(event U) have been traced from the shelf to deep water. On individual seismic records it is usually difficult to follow this event through the zone of the shelf break, where the change in bottom slope and probable changes in sediment lithology combine to degrade record quality. Fortunately, however, the correlation of the U event from the shelf to deep water can be checked by crossreferencing the intersecting lines of survey coverage (Fig. 1).

Section G and the southern ends of sections B to D (Fig. 2), located on the Newfoundland Ridge, show seismic reflectors to depths approaching 4 s (two-way time) below the U event, with no indication of any underlying basement. These sub-U reflectors are interpreted as denoting gently dipping sedimentary strata. Velocity analyses performed in the course of data processing indicate velocities in these strata as low as 3–4 km s<sup>-1</sup>, which would yield a minimum thickness for these strata of 6–8 km. The apparent attitudes of the seismic reflectors at the crossing of lines C and D with line G indicate a north-westerly strike, approximately parallel to the physiographic trend of the Newfoundland Ridge. These strata form cuestas and hogbacks at the U event interface; however, it is not clear from the seismic data whether the scarps associated with these features are entirely erosional or whether displacement by faulting has occurred. Dipping reflectors below the U event in the central part of line F, between crossings with lines B and C, are also interpreted as originating in sedimentary strata.

Sub-U penetration of a different character occurs on the eastern end of line E, and along the northern three-quarters of line D (Fig.

Fig. 2 Seismic and magnetic profiles from locations indicated in Fig. 1. Vertical scale for the seismic profiles is in seconds of two-way travel time. The U event has been emphasised. Vertical bars on profile B indicate coverage of Fig. 3.

Fig. 3 Photograph of a portion of a seismic record section on the Newfoundland Ridge.

2). These reflectors show variable attitudes, amplitudes and continuity. Beneath the south-western slope of the Grand Banks, large anomalies traced by the U event on lines A and E have been interpreted by Jackson *et al.*<sup>10</sup> as relief on oceanic basement. The seismic record sections show reflectors on the flanks of these features, but no apparent penetration beneath their central, highest parts. The character and disposition of these flanking reflectors give the impression of talus deposits.

The reflection seismic data described above distinguish between acoustic basement highs beneath the south-western slope of the Grand Banks and blocks of sedimentary strata beneath the Newfoundland Ridge. Available magnetic coverage<sup>7</sup> shows a complex assemblage of large magnetic anomalies associated with both areas, and with the J-anomaly ridge as well, but does not seem adequate to refine the limits of these two types of sub-U structure indicated by seismic data. Possibly there is a north-westerly trend to the magnetic anomalies in the vicinity of the Newfoundland Ridge.

Occasional penetration of seismic energy is seen beneath the U event on the Grand Banks (sections A, B, C and E, Fig. 2). The north end of section A shows more extensive penetration associated with the South Whale sub-basin (Fig. 1). Excellent seismic records across the sub-unconformity basins on the Grand Banks have been presented by Amoco and Imperial<sup>9</sup>.

## Discussion

Assuming that the U seismic event has been traced correctly from the Grand Banks to the limit of coverage in deep water, and that the chronological significance of this event remains approximately constant, then the age of the sedimentary strata underlying the U event on the Newfoundland Ridge must be early Cretaceous or older. The U event unconformity is evidence that these strata were exposed to subaerial weathering before the subsidence time. The results from DSDP site 384, on the J-anomaly ridge (Fig. 1), indicate that subsidence of at least 4 km has affected this area since the late early Cretaceous<sup>11</sup>. The apparent thickness of the strata beneath the U event on the Newfoundland Ridge (up to 6–8 km) is comparable to the thickness of section that occurs in the sub-unconformity basins on the Grand Banks, and the areal extent of these strata as defined by the seismic lines in Fig. 2 is at least equivalent to that of the smaller basins on the Grand Banks (Fig. 1). It is, therefore, postulated that the sedimentary strata underlying the U event on the Newfoundland Ridge may represent a basinal accumulation analogous to the sub-unconformity basins on the Grand Banks, which has subsided relative to the Grand Banks by displacement across a hinge line or zone of faulting beneath the present continental slope. If these strata extend to the physiographic limit of the Newfoundland Ridge (Fig. 1), this feature would represent a subsided, remnant basin roughly equivalent in area to the total of the several remnant basins on the Grand Banks.

The sub-unconformity basins on the Grand Banks are fault-bounded grabens and half-grabens containing Jurassic and older formations, with structural complications related to salt diapirism<sup>9</sup>. The sparse data available indicate that the basement rocks underlying these formations are composed of a wide variety of lithologies and probably range in age from Palaeozoic to

Precambrian<sup>1,9</sup>. These data are a meagre basis for speculation as to the nature of the basement rocks that underlie the sub-U sedimentary strata on the Newfoundland Ridge, except that they are probably sialic. But, an important implication of the inferred basinal setting of these strata is that the basement rocks adjacent to the basin subsided more deeply than the sediments, and that foundered sialic rocks thus extend some distance laterally from the Newfoundland Ridge.

The multichannel seismic coverage (Fig. 1) is not sufficient to determine the extent of sialic crust laterally from the Newfoundland Ridge, but variations in the character of these seismic data in the area peripheral to the ridge may be relevant. Off the eastern margin of the Grand Banks the northern three-quarters of line D (Fig. 2) shows irregular and discontinuous reflectors beneath event U. The depth to the U event opposite sonobuoy Station No. 33 (Fig. 1) of Jackson *et al.*<sup>10</sup> corresponds closely to the depth to their inferred oceanic basement refractor of  $5.82 \text{ km s}^{-1}$ . On the south-western side of the Grand Banks Jackson *et al.*<sup>10</sup> recorded a mantle refraction at a depth of approximately 17 km, and described the irregular surface traced by the U event in that area (lines A and E, Fig. 2) as oceanic basement. The refraction seismic definition of oceanic basement in these two areas obviously is not sensitive to the contrasts in surface profile and seismic penetration shown by the multichannel reflection seismic records, and it is doubtful that both of these refraction measurements define true oceanic basement. Possibly the differences in the reflection seismic character of these two areas relate to variation in the composition of parent sialic crust, now subsided.

The extent of subsided continental crust peripheral to the Newfoundland Ridge can be examined in a larger context. Pre-drift fits of the North Atlantic tend to place the western margin of the Iberian Peninsula opposite the south-western margin of the Grand Banks<sup>1,2</sup>. In some reconstructions, Galicia Bank, which lies offshore west of the northern part of the Iberian Peninsula, obstructs the tight juxtaposition of these two margins and leaves an untidy gap to the south. An area of continental crust about the Newfoundland Ridge would help to fill this gap.

The large magnetic anomalies in the vicinity of the Newfoundland Ridge may relate to the presence of subsided continental crust as hypothesised above. Possibly these large anomalies express the susceptibility contrast between sedimentary rocks and volcanic rocks, assuming that the sediments and sialic basement rocks were invaded by mafic volcanics, probably at the time of subsidence. This interpretation may also apply to the physiographic and magnetic characteristics of the J-anomaly ridge, which coincides with a larger magnetic anomaly than expected in relation to its physiographic relief and reasonable magnetisation values for oceanic basement<sup>11</sup>. The distinctive topographic aspects of the J-anomaly ridge<sup>6</sup>, particularly the anomalously flat surfaces apparently disrupted by faults, would be normal features for a ridge composed primarily of sedimentary strata. This postulated origin for the J-anomaly ridge implies that it does not necessarily have an isochronal relationship to seafloor spreading. Hall<sup>7</sup> and Keen *et al.*<sup>8</sup> have discussed the problematic nature of the age of the J anomaly, which has been assigned ages ranging from 115 to 137 Myr BP.

## Conclusions

Multichannel reflection seismic data from the Newfoundland Ridge allow penetration below the surface commonly regarded as oceanic basement, with important consequences for the geological interpretation of this region. These data indicate that the Newfoundland Ridge is composed of blocks of sedimentary strata, pre-late early Cretaceous in age, which may represent a sedimentary basin, now subsided, analogous to the sub-unconformity basins on the Grand Banks.

A synthesis of available data from the region of the southern Grand Banks suggests that sialic crust adjacent to the Newfoundland Ridge has subsided to oceanic depths, and that variations in its composition are shown by variation in reflection seismic character. These differences are beyond the resolution capability of the refraction seismic method. If it is accepted that the

subsidence of sialic crust was accompanied by igneous invasion, a new pattern of magnetic anomalies probably was generated, with their orientation determined by the mechanical processes of subsidence and the geological fabric of the parent crustal material. These anomalies would not be expected to have chronological significance in terms of processes of seafloor spreading.

Additional survey control is required to map the limits of postulated subsided continental crust in the vicinity of the Newfoundland Ridge. Probably it will be necessary to apply common depth point reflection seismic techniques to effectively pursue this problem. Increased application of the common depth point reflection seismic method in the deep sea, particularly in the marginal zones of the ocean basins, will reveal further variations in the character of oceanic basement. The data described here indicate another probable sliver, chip or mini-plate that geomet-

ricians must accommodate in closing the North Atlantic to predrift configurations.

# Absolute radiocarbon dating using a low altitude European tree-ring calibration

G. W. Pearson, J. R. Pilcher, M. G. L. Baillie & J. Hillebrand

Palaeoecology Laboratory, Queen's University, Belfast, UK

*Attempts to produce a calibration curve for the radiocarbon timescale by analysis of known age materials have highlighted the inaccuracies of conventional radiocarbon dating methods. The resulting ambiguities have caused a loss of confidence in radiocarbon dating particularly among European pre-historians. We describe here an absolute radiometric dating technique involving the investigation of all probable sources of error. Accurate measurements were made with an overall precision of less than 25 yr standard deviation, on a floating North of Ireland tree-ring chronology.*

CORRECTION for natural atmospheric radiocarbon variation is only one of the several corrections that have been necessary to relate the radiocarbon assay of organic materials to a calendar time scale. The assumption of the constancy of natural radiocarbon was first questioned by DeVries<sup>1</sup>, and several teams set out to test the constancy by measuring the radiocarbon content of known age samples. Willis, Tauber and Munnich<sup>2</sup> and Suess<sup>3</sup> showed that there was a significant trend away from the theoretical relationship. The bristlecone pine chronology was used for further investigation of the problem<sup>4,5</sup>. Suess showed major short-term variations or 'wiggles' in the calibration and suggested that in certain periods radiocarbon measurements could not provide unambiguous dates.

Further bristlecone pine samples were then distributed to three laboratories; La Jolla, Arizona and Pennsylvania and the results presented in 1969<sup>6</sup>. Suess<sup>7</sup> presented his calibration as a curve drawn by eye through the measurement points, incorporating a number of pronounced wiggles. Part of this graph is reproduced in Fig. 1. Following publication several authors<sup>8-11</sup> questioned the validity of Suess's line.

During the next few years few new data were produced from the radiocarbon laboratories and discussions continued among radiocarbon users on the validity of the wiggles and on what methods should be used to apply corrections to radiocarbon age measurements<sup>12,13</sup>. At various times the bristlecone pine tree-ring chronology was questioned, but this was resolved by the replication of the greater part by LaMarche and Harlan<sup>14</sup>. The possibility was also raised that *in situ* production of <sup>14</sup>C in the high altitude bristlecone pines was leading to spurious results. This has been discounted both by experiment<sup>15</sup> and by theoretical calculations based on the nitrogen content of the wood<sup>16</sup>. Two more recent calibrations are given by Damon *et al.*<sup>17</sup> who present a

calibration based on 549 samples using a curvilinear regression, and by Clark<sup>13</sup>. The latter summarises previous calibrations and examines the evidence from duplicate measurements which indicate a greater spread in the results than can be accounted for by the stated precisions. Disagreements between radiocarbon dates for bristlecone pine wood and for same-age, historically dated, Egyptian material are apparent. These disagreements led McKerrell<sup>18</sup> to suggest that systematic differences may exist and that the bristlecone calibration may not be appropriate in European contexts.

Although it is 19 years since the DeVries report, there is still no satisfactory experimentally-derived calibration that can be used unambiguously to convert radiocarbon ages to calendar dates. The publication of numerous calibration curves based on identical material, has proved that laboratories can only agree on the general trend of the calibration. Because of these disagreements it has been left to statisticians to provide smoothed calibrations. One such attempt has been the fit by Damon<sup>17</sup> of a third order orthogonal polynomial to experimentally derived data. At a recent conference no internationally acceptable radiocarbon calibration could be arrived at. It was apparent that an attempt should be made to resolve these discrepancies on the assumption that the experimental method was at fault.

By 1970 studies on oaks had established that long tree-ring chronologies could be constructed in the North of Ireland. To exploit this source of low altitude calibration material, a radiocarbon dating system capable of taking advantage of large sample size was designed; the method chosen was the liquid scintillation counting of benzene synthesised from sample cellulose. In 1972 a research programme was started to investigate all factors likely to contribute to the inaccuracy of radiocarbon measurement. Details of the procedure for synthesising large volume benzene samples and methods of counting will be given elsewhere (G.W.P., in preparation). So that the results given here may be critically examined, the corrections derived from these investigations are given in Table 1.

## Methods

The measurements were carried out on a 1,200-yr section of a 2,990-yr floating tree-ring chronology derived from sub-fossil oaks which grew below 130 m altitude between latitude 54° and 55°N and longitude 6° and 8°W (ref. 19). The chronology is based on some 300 trees and is replicated at all points. Because of bulk-field sampling and relatively large annual rings it was possible to produce 20-yr units of 180-200 g for radiocarbon measurement. This is in comparison with normal bristlecone pine samples of 20 g.

Table 1 Experimentally derived corrections for significant error sources

Error source investigated	Correction derived experimentally	Normalised value	Estimated error on correction
Barometric pressure variation	Background increases by 0.0127 c.p.m. per mbar decrease in* pressure	1010 mbar	$\pm 0.013$ c.p.m.
Background variations with weight loss	Background decreases by 0.0003 c.p.m. per mg decrease in weight	13.1325 g C <sub>6</sub> H <sub>6</sub> 14.2666 g C <sub>6</sub> H <sub>6</sub> + scintillant	$\pm 0.003$ c.p.m.
Background variations with purity	Changes by 0.041 c.p.m. per cent change in channels ratio	External source channels ratio of 1.95	$\pm 0.041$ c.p.m.
Efficiency variation with weight loss	Efficiency increases by 0.00104% per mg decreases in weight	13.1325 g C <sub>6</sub> H <sub>6</sub> 14.2666 g C <sub>6</sub> H <sub>6</sub> + scintillant	$\pm 0.010\%$ of nett c.p.m.
Differential loss of sample from mixture and correction to normalised weight including all weighing errors†	98.3% of loss from vial is sample benzene	13.1325 g C <sub>6</sub> H <sub>6</sub>	$\pm 0.076\%$ of nett c.p.m.
Efficiency variation with purity	‡%Deviation from normal purity 0.0–1.0 (1.00005) 1.0–2.0 (1.00015) 2.0–3.0 (1.00025)	External source channel ratio of 1.95	$\pm 0.005\%$ of nett c.p.m.
Mass spectrometry correction	Isotopic enrichment measured (actual reproducibility over 12 months)	–25% rel. P.D.B. (samples) –19% rel. P.D.B. (oxalic reference)	$\pm 0.05\%$ of nett c.p.m. $\pm 0.05\%$ of nett c.p.m.
Individual vial difference for efficiency	Using high <sup>14</sup> C labelled C <sub>6</sub> H <sub>6</sub>	Mean value	$\pm 0.029\%$ of nett c.p.m.
Individual vial difference for background	95% limits of parent distribution	Mean value	$\pm 0.058$ c.p.m.

The method used for calculation was that given by Callow *et al.*<sup>27</sup>.

\*High correlation of background with barometric pressure was found. Failure to correct could lead to a bias of up to 100 yr and make use of long-term mean background values impossible.

†Large inaccuracies, up to 40 mg, can be caused by the effect of humidity and temperature on plastic caps.

‡Correction factor given in parentheses.

Measurements were made on contiguous 20-yr increments taken from different trees in the floating chronology. Each increment was reduced to shavings and treated with a chlorite bleach<sup>20</sup> which left a sample free from tannins and lignins and close to pure cellulose. This treatment has been shown<sup>16</sup> to remove the greater part of any effect of heartwood deposition in oak since cellulose is not laid down at the heartwood/sapwood transition. Following cellulose preparation samples were charred at 450 °C to leave a carbon residue and converted to CO<sub>2</sub> by combustion or bomb calorimetry. The gas was sub-sampled for mass spectrometric measurement of the stable carbon isotope ratio.

The synthesis of benzene from sample CO<sub>2</sub> followed the conversion path CO<sub>2</sub> → LiC → C<sub>2</sub>H<sub>2</sub> → C<sub>6</sub>H<sub>6</sub> using the method of Barker<sup>21</sup>. This method was modified to allow the synthesis of up to 20 ml of sample benzene. Contamination of the water supply, and of the lithium metal used in the synthesis with <sup>222</sup>Rn was severe and great care was needed to ensure its removal. Mass spectrometric analysis of the synthesised benzene showed that it was at least as pure as scintillation grade benzene and was of consistent quality.

The samples were measured on a Philips 4510 automatic liquid scintillation analyser with the three channels for individual isotope monitoring set for the measurement of <sup>3</sup>H, <sup>14</sup>C and <sup>222</sup>Rn. Two extra channels were used for the differential energy measurement of a 7 μCi <sup>133</sup>Ba external source, the ratio being used to check variation in pulse height (a limit of  $\pm 4.5\%$  of mean purity pulse height was applied). Balance point counting of <sup>14</sup>C (a differential technique in which the pulse height spectrum within the selected channel is so balanced that small variations in pulse height contribute almost as many pulses to the channel as are lost) reduced the effect of pulse height variation giving long-term changes in efficiency of less than 0.03%. Continuous background

measurement of a flame-sealed vial showed no significant deviation from a normal distribution when corrected for barometric pressure variation (a major source of error, see Table 1). Gain stability checks were maintained using flame-sealed vials containing high specific activity <sup>3</sup>H and <sup>14</sup>C-labelled toluene. Because of the relative increase in pulse height of toluene to benzene the <sup>14</sup>C high standard was not measured in a balance point position and was therefore very sensitive to gain changes. The <sup>14</sup>C channel was set so that balance point was achieved at a specific purity equivalent to an external source channels ratio of 1.95. Each sample was normalised to this purity (Table 1).

The vials used were of standard low potassium glass selected for weight similarity from a batch of 500. The background for each vial was monitored for 2-yr and was checked after each sample or standard filling. The vials were undercoated with white paint above the 18 ml level to improve photon collection and to give a precise counting geometry and then coated with black paint to reduce optical feedback between one photomultiplier and the other. Each vial was filled to within  $\pm 5$  mg of the normalised weight for benzene and scintillant (Table 1). The scintillation mixture in 1 ml of toluene added to 15 ml of sample benzene (13.1325 g) gave a scintillant concentration of 10 g l<sup>-1</sup> butyl PBD and 0.6 g l<sup>-1</sup> PBBO. An 'Agla' pipette with hypodermic needle was used to inject the sample through a special filling cap which was then replaced with a sealing cap incorporating discs of rubber, PTFE and pure tin. All samples were calculated using the Libby half life and 95% of the oxalic acid reference standard count rate representing AD 1950.

Each vial background was measured for successive 100-min intervals giving an accumulated count of approximately 100,000 for each vial. Each 100-min count was corrected for barometric

pressure variation and plotted to give a quality control distribution for that vial. Mean values of the vial distributions were compared in a single 'parent' distribution having a standard deviation equal to  $\pm 0.3\%$ . The points fell into an apparent normal distribution indicating that all the vials belonged to the same distribution thus allowing a single grand mean background value to be used. The values of the background and its precision including all errors and corrections were:  $9.289 \pm 0.078$  c.p.m.

Standards, samples and backgrounds were counted in sequence. Two oxalic reference standards were measured at any one time providing continuity and overlap during their regular replacement. Each measurement was corrected and plotted on a quality control chart, and a mean value determined for each individual oxalic distribution. As a check for unique vial efficiencies, high specific activity samples were used. On an observed count of not less than  $1.6 \times 10^7$  c.p.m. for each vial, no significant difference was obtained. The mean oxalic distributions were then compared and were found to lie within  $\pm 2$  standard deviations of a grand mean value, once more signifying that they probably belonged to a single distribution. The mean value of this distribution for the nett reference standard count rate used in the date calculation was:  $122.854 \pm 0.163$  c.p.m.

After synthesis each sample was left to stand at  $-10^\circ\text{C}$  for at least 1 month before being prepared for counting, to allow a 100-fold decrease in any remaining  $^{222}\text{Rn}$  contamination. At least 300,000 sample counts were accumulated over a minimum counting period of a fortnight. As in the case of standards and backgrounds, the barometric pressure and pulse-height variation were measured during each cycle and used for the correction of each result. Correction for weight changes was made after vial removal; any changes in cap weight being assessed and corrected for. All measurements were normalised to the value quoted in Table 1. The calculated dates were finally corrected for isotopic fractionation.

The 25-yr standard deviation quoted on all dates is a blanket precision covering all errors found to be significant in the experimental method. It includes not only the counting statistics and mass spectrometric correction normally quoted (equivalent in this case to less than  $\pm 17$  yr), but also the estimated errors due to all the corrections listed in Table 1. Some of the sources of error, if not corrected for, could cause a bias of up to 100 yr.

## Results and discussion

The results of the  $^{14}\text{C}$  measurements are given in Table 2, in yr before AD 1950. Some results for the contiguous series of samples are not yet available due to random selection of samples for

**Table 2** Radiocarbon dates b.p. for 20-yr increments of tree-ring dated Irish oak wood

Tree-ring age (yr)	$^{14}\text{C}$ date (b.p.)	Tree-ring age (yr)	$^{14}\text{C}$ date (b.p.)	Tree-ring age (yr)	$^{14}\text{C}$ date (b.p.)

Tree-ring time scale is floating. 0 on this scale = 5,810 on the computer scale given in Pilcher *et al.*<sup>19</sup>.  $^{14}\text{C}$  dates are calculated on the 5,568 yr half life. 1  $\sigma$  precision on all dates is  $\pm 25$  yr.

**Fig. 1** Relationship between radiocarbon and tree-ring years. *a*, Relationship established using low-altitude oak from the North of Ireland; two standard deviation limits dashed, regression line drawn with curvilinear 95% confidence limits. *b*, Curve published by Suess<sup>7</sup> based on bristlecone pine wood. *c*, Historically derived calibration based on Egyptian material published by McKerrell<sup>18</sup>.

measurement, but no results have been deleted or ignored. The measurements are plotted on Fig. 1 together with the regression line through them. The regression line has a slope of 1.215, and a regression coefficient of 0.99. The *F* value for the regression is greater than 3,000 indicating a good straight line fit to the distribution. Also shown on Fig. 1 are sections of some previous calibration curves. Each is drawn on the same radiocarbon axis and on its own independent tree-ring axis. This is necessary because our tree-ring sequence is not yet tied to the present day.

The investigations carried out in preparation for these calibration measurements showed significant error sources in conventional  $^{14}\text{C}$  measurement techniques (G.W.P., unpublished). The results given here show that these error sources can be overcome and that the overall one standard deviation measurement precision can be reduced to less than 25 yr. The closeness of fit to a straight line indicates that there are no remaining significant random error sources not covered by the measurement precision. By increasing the sample counting time the precision could be reduced to the same level as other error sources giving an overall one standard deviation limit of  $\pm 12$  yr in 10,000, and similarly with a long count the limit of detection would be greater than 60,000 yr. If, as these results suggest, each radiocarbon age represents a unique calendrical age at least over a large part of the  $^{14}\text{C}$  time scale, then a very close approximation can be made to an absolute time scale.

The straight-line slope through our results lies within 1% of that derived by Damon *et al.*<sup>17</sup> and is close to the lines deduced by

Wendland and Donley<sup>8</sup> and by Clark<sup>13</sup> on the basis of the bristlecone pine results. The line based on Irish material does not show, within measurement limits, any of the wiggles predicted by Suess<sup>7</sup> for this period or retained by McKerrell<sup>18</sup> in his 50-yr averaging of the bristlecone pine data. This rules out, over the period investigated, the use of wiggle matching<sup>22</sup> as a dating technique. Suess (personal communication) has criticised our use of 20-yr blocks of tree-rings as he maintains that this will cause some smoothing of the wiggles. By using contiguous 20-yr blocks, however, no information is lost and the only way that short-term variations could produce a straight line calibration would be if they occurred as an exact harmonic of a 20-yr cycle over the whole 1,200 yr. This is inherently unlikely. Also, most radiocarbon samples represent greater than this time-span. Archaeological samples, which are very often of oak in European contexts, are normally charred branches or small timbers of at least 20 yr. Peat and sediment samples used for palaeoecological studies are normally of greater than 20-yr growth. The effect of smoothing due to deposition of recent carbon at the heartwood/sapwood transition has been circumvented by the use of wood cellulose as the dating material<sup>16</sup>. The only remaining non-random error which could explain the difference between the bristlecone pine and oak calibrations is the possibility<sup>16</sup> that persistent inversion layers along the Pacific coast of the USA may have caused deviations from the global average radiocarbon level. It is not clear whether this phenomenon could account for the short-term variations observed by Suess. Similarly, within the curvilinear limits of the regression there is no clear indication of the flat spots in the calibration predicted by Ottaway and Ottaway<sup>23</sup>.

Until the tree-ring sequences are tied to the present it will not be possible to assign calendar years to the tree-ring axis of our calibration curve. Without this it is not possible to answer questions of world uniformity of the atmospheric carbon reservoir<sup>24</sup>. If world-wide uniformity is assumed then the dendrochronological age of our calibration has been shown to be within 10 yr of the range 4,100–5,240 yr b.p. (J. C. Lerman, personal communication).

Even without absolute time control there are several important conclusions that can be drawn from these results. It is clear that for the radiocarbon age span 3,600–4,550 yr b.p. the calibration is smooth within the statistical uncertainty of  $\pm 3\%$  and is not significantly different from a straight line. As both the smoothness and the slope of the line are close to those statistically deduced from the bristlecone pine measurements it is reasonable to suggest that any calibration exhibiting marked deviations from this picture will ultimately be found in error. On the basis of these results it seems likely that the greater part of the calibration will tend to be smooth rather than 'wiggly'. This does not rule out, of course, the possibility of some short-term atmospheric radiocarbon variation such as that well documented for the seventeenth century AD. We cannot yet finally answer the question of whether there is a systematic difference between the bristlecone pine and Egyptian chronologies. The implication of the close agreement between the slopes of two tree-ring derived calibrations is that the deviant slope of the Egyptian calibration championed by McKerrell<sup>18</sup> is likely to be erroneous, indicating possible inaccuracies in the Egyptian

calendar or in  $^{14}\text{C}$  measurements for the period before 1800 BC.

Even within the short time span so far examined there are direct implications. For example, the floating calibration covers the disappearance of pine from Irish pollen diagrams for which a close bunching of radiocarbon dates has been observed<sup>25</sup>. This bunching can no longer be attributed to a 'calibration wiggle' and must, therefore, represent a synchronous event. Whether this same argument can be applied to problems outside the time range studied cannot yet be determined. If, however, most of the short-term variations disappear when a full calibration is completed, then it will ultimately reduce the uncertainty in the derivation of a true age estimate from a radiocarbon date. In fact, if it is assumed that a full calibration of the accuracy presented here is possible and if individual samples were measured with the ultimate precision of  $\pm 12$  yr, then it should be possible to produce a calibrated radiocarbon date whose 95% confidence limits fall within a bandwidth of 80 yr. This would restore radiocarbon dating to the position of the absolute dating method as was foreseen at its inception.

But the reality of the errors associated with radiocarbon dating must now be faced. Damon<sup>26</sup> and Clark<sup>13</sup> pointed out that the errors based on analysis of replicated bristlecone pine samples are greater than those covered by the quoted precision. Having demonstrated the linearity of the calibration it seems possible that the variation in the dates associated with the bristlecone pine samples was due to uncontrolled errors. Since the previous measurements involving calibration samples can be assumed to be among the most careful, even these errors may well be an underestimate of those associated with routine radiocarbon measurements.

We thank Professor A. G. Smith for his assistance. We also thank Professor Paul E. Damon, Dr J. C. Lerman and Dr A. Long for helpful discussions, and Mrs F. Qua for assistance with radiocarbon measurements. The project was partially financed by the Natural Environment Research Council.

## Purification of a positive regulatory subunit from phage SP01-modified RNA polymerase

John J. Duffy & E. Peter Geiduschek

Department of Biology, University of California, San Diego, La Jolla, California 92093

*A phage-induced subunit has been purified from phage SP01-modified Bacillus subtilis RNA polymerase. This subunit binds in vitro to RNA polymerase core from uninfected B. subtilis thereby inducing template-selective transcription and asymmetric synthesis of SP01 middle RNA.*

THE interaction of virus-coded proteins with the host's RNA polymerase is an important mechanism for the control of gene expression during bacteriophage development<sup>1,2</sup>. Purified RNA polymerase from *Bacillus subtilis* infected with phage SP01 or SP82 contains tightly associated, virus-coded proteins<sup>3–5</sup>. A significant

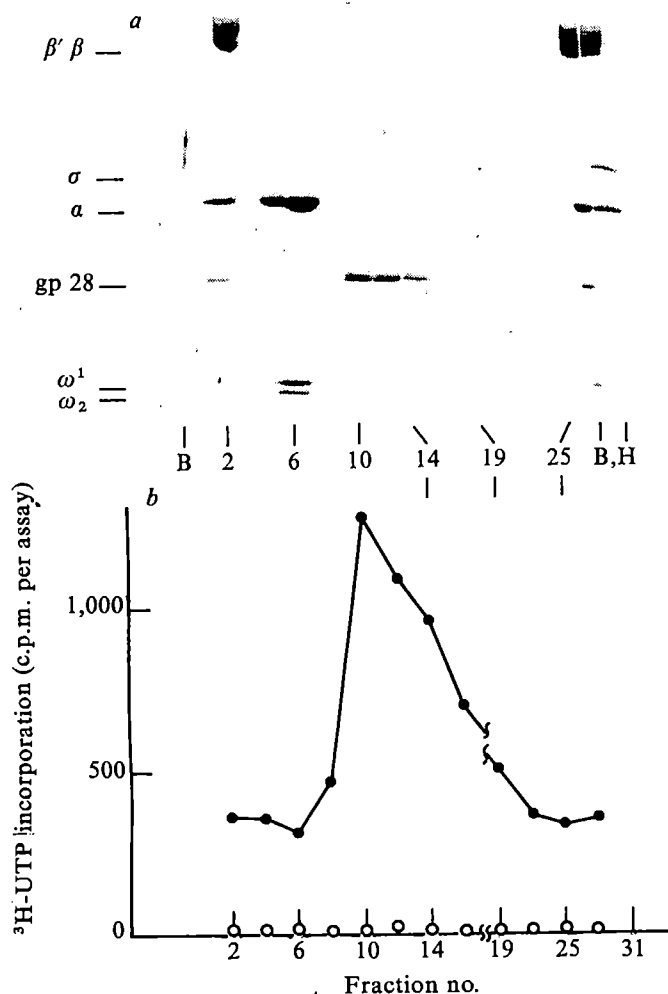

property of one particular modified RNA polymerase from phage SP01-infected bacteria is that it asymmetrically transcribes hydroxymethyluracil (hmU)-containing SP01 DNA to yield the positively regulated 'middle' SP01 RNA *in vitro*. In contrast, the unmodified host RNA polymerase transcribes essentially only SP01 'early' genes<sup>3-7</sup>. The modified RNA polymerase which we previously designated as B-P is composed of the subunits of polymerase core together with two virus-coded subunits,  $\nu^{28}$  and  $\nu^{13}$  (ref. 3). (The quantity of  $\nu^{13}$  varies from preparation to preparation.) At least one of the two virus-coded subunits is responsible for the selective, rapid initiation of SP01 middle transcription and functions at the level of DNA binding<sup>8</sup>. We have previously reported<sup>9</sup> the identification of a protein from a partially purified extract of SP01-infected bacteria which binds to host RNA polymerase core and converts it to the modified form. This protein has the physical properties of  $\nu^{28}$ . The isoelectric point (unpublished observations) and molecular weight of  $\nu^{28}$  identify it as identical with the peptide IV of Pero *et al.*<sup>4</sup>, which has been shown<sup>10</sup> to be the product of SP01 gene 28. The product of SP01 gene 28 controls 'middle' viral gene expression<sup>11</sup>. Thus,  $\nu^{28}$  = peptide IV = gene product 28 (gp28). We report here the purification of gp28 from RNA polymerase and show that gp28 directs the transcription of SP01 'middle' genes by *B. subtilis* RNA polymerase core enzyme.

### Purification of regulatory subunit

The RNA polymerase which we used as a source of gp28 was purified from *B. subtilis* which had been infected for 10 min with

phage SP01 *sus* F4 (gene 33)-*sus* F14 (gene 34). Genes 33 and 34 code for proteins that regulate late transcription and bind to host RNA polymerase<sup>7,11-13</sup>. The phage-modified RNA polymerase from *sus* F4-*sus* F14-infected bacteria is free of gp33 and gp34. It is composed of the RNA polymerase core subunits ( $\beta$ ,  $\beta'$ ,  $\alpha$ ,  $\omega^1$ ,  $\omega^2$ ) and of the virus-coded subunit gp28 (data not shown).

When RNA polymerase is dissociated with 6 M urea and chromatographed on phosphocellulose in the presence of 6 M urea, the subunits of the polymerase are separated. Figure 1a shows a gel electropherogram of the fractions obtained. The  $\alpha$ ,  $\omega^1$  and  $\omega^2$  subunits (fractions 4-8) do not bind to the phosphocellulose. Elution of gp28 is reproducibly sufficiently delayed to separate it from the  $\alpha$ ,  $\omega^1$  and  $\omega^2$  subunits (fractions 10-19). The  $\beta'$  and  $\beta$  subunits bind to phosphocellulose and are eluted at higher salt concentration in 6 M urea (0.12 M and 0.27 M KCl, respectively). The pattern of subunit fractionation is similar to that previously described<sup>14</sup>. But, the RNA polymerase from *sus* F4-*sus* F14-infected *B. subtilis* lacks subunit  $\nu^{13}$  which would otherwise elute with gp28 and, as a result of this, gp28 is eluted in electrophoretically pure form. The fractionation of the  $\beta$ ,  $\beta'$ ,  $\alpha$ ,  $\omega^1$  and  $\omega^2$  subunits is also similar to that reported by Tjian and Pero<sup>13</sup>. Comparison of Fig. 1a and b shows a direct correlation between the activity which stimulates RNA polymerase core and the presence of gp28. The stimulating activity is manifested only in the presence of hmU-containing SP01 DNA and not with thymine-containing  $\phi$ 29 DNA. This template selectivity is also a property of the phage-modified RNA polymerase B-P<sup>3,8</sup>. The activity of gp28 can be assayed without prior removal of urea. Either gp28 is not denatured in the conditions of the phosphocellulose chromato-

**Fig. 1** Phosphocellulose chromatography of urea-treated RNA polymerase from *B. subtilis* infected for 10 min with *sus* F4-*sus* F14 SP01 phage. RNA polymerase (1.2 mg, purified according to ref. 3) was dialysed against buffer G (0.01 M Tris-HCl, pH 8, 0.1 mM EDTA, 0.01 M dithiothreitol) containing 0.05 M KCl and 6 M urea (freshly deionised) and was subsequently applied to a column of phosphocellulose (1.4 cm  $\times$  0.7 cm i.d., column volume 2 ml, rate of application 2 ml per h) pre-washed with 200 ml of the same buffer. The polymerase was allowed to equilibrate with the phosphocellulose for 30 min. The column was then washed with the same buffer at a rate of 2 ml per h, and 1 ml fractions were collected into tubes containing 0.25 ml of 50% (v/v) glycerol in buffer G plus 0.05 M KCl. *a*, Polyacrylamide slab gel electrophoresis. 100  $\mu$ l aliquots of selected fractions from the phosphocellulose column were concentrated by precipitation on ice in 10% (w/v) trichloroacetic acid. The precipitates were collected by centrifugation, washed with cold 1 M HCl and again collected by centrifugation. The samples were dried under vacuum and dissolved in the electrophoresis sample buffer which contained 3% (w/v) sodium dodecylsulphate to aid in solubilising the samples. The samples were electrophoresed in denaturing conditions (0.1% SDS) in a polyacrylamide slab gradient gel (7-15% (w/v) acrylamide) run according to Laemmli<sup>17</sup>. Marker samples were treated in an identical manner. The gels were fixed and stained in 0.2% Coomassie brilliant blue in methanol-acetic acid-water (4.5:1:4.5) and destained in methanol-acetic acid-water (10:7.5:82.5). The following samples are shown: B, 3  $\mu$ g of RNA polymerase from *B. subtilis* infected for 10 min with *sus* F4-F14 SP01 phage; numbered fractions from the phosphocellulose column; H, 3  $\mu$ g of RNA polymerase from uninfected *B. subtilis*. *b*, Assay of fractions for their ability to stimulate the activity of RNA polymerase core from uninfected *B. subtilis*. 10  $\mu$ l aliquots of fractions from the phosphocellulose column were added on ice to 0.4  $\mu$ g of RNA polymerase core in 25  $\mu$ l of TGB (0.01 M Tris-HCl pH 8, 0.1 mM EDTA, 15% (v/v) glycerol, 400  $\mu$ g ml<sup>-1</sup> bovine serum albumin). Then 4  $\mu$ g of DNA was added in 20  $\mu$ l of 0.01 M Tris-HCl pH 7.5 and 0.001 M EDTA. Each sample was then made up to 90  $\mu$ l by addition of reaction components to give the following concentration: 0.11 M Tris-HCl pH 8, 0.11 mM each of EDTA and dithiothreitol, 0.88 mM spermidine chloride, 1.1 mM each of ATP, GTP, CTP, and 0.13 mM  $^3\text{H}$ -UTP (10.3 c.p.m. pmol<sup>-1</sup>). After incubation for 10 min at 30  $^{\circ}\text{C}$ , 10  $\mu$ l of 0.1 M MgCl<sub>2</sub> was added to start the reaction (the final urea concentration was 0.48 M). After 5 min the reaction was stopped and incorporation of  $^3\text{H}$ -UTP into acid insoluble material was measured as described elsewhere<sup>3</sup>.  $^3\text{H}$ -UTP incorporation was measured using either SP01 DNA ( $\bullet$ ) or  $\phi$ 29 DNA ( $\circ$ ) as template. In the presence of RNA polymerase core and with the column fractions replaced by 10  $\mu$ l of the equivalent buffer, incorporation was 280 c.p.m. with SP01 DNA and less than 20 c.p.m. with the preparation of  $\phi$ 29 DNA used here. Using the same conditions, 0.4  $\mu$ g *B. subtilis* holoenzyme gave 1,942 c.p.m. incorporation in the presence of SP01 DNA and 982 c.p.m. in the presence of  $\phi$ 29 DNA. (Preparations of  $\phi$ 29 DNA used by us previously gave appreciably more template activity with *B. subtilis* RNA polymerase core<sup>3</sup>.)

graphy, or, more probably, it renatures rapidly in the presence of polymerase core at the lower urea concentration (0.48 M) of the assay.

Fractions containing gp28 were combined and their glycerol content was increased to 25% (v/v). The gp28 was concentrated and the urea was removed by passing the combined fractions over a DEAE-cellulose column (1.8 cm  $\times$  0.4 cm i.d., 1 ml column volume) and subsequently washing the column with urea-free buffer (buffer G with 0.04 M  $\text{NH}_4\text{Cl}$  and 25% (v/v) glycerol added). A gradient of 0.04–1.0 M  $\text{NH}_4\text{Cl}$  in the same buffer was applied to the column and gp28 was eluted at 0.2 M  $\text{NH}_4\text{Cl}$ .

### Properties of regulatory subunit

The activity and template selectivity of RNA polymerase reconstituted from purified gp28 and *B. subtilis* core enzyme and of the phage-modified RNA polymerase from *sus* F4-*sus* F14 phage-infected bacteria are compared in Table 1. The quantity of gp28 added to the RNA polymerase is saturating with respect to polymerising activity on SP01 DNA. The template selectivity of the gp28 is shown by the more than fourfold stimulation of RNA polymerase core in the presence of hmU-containing SP01 DNA (line 1) and by the lack of activity of thymine-containing  $\phi$ 29 DNA (line 2). The same selectivity is observed with the RNA polymerase from *sus* F4-*sus* F14-infected bacteria (lines 3 and 4) and with gp28-containing RNA polymerase from *B. subtilis* infected for 10 min with wild type SP01 (refs 3, 8). The phage-modified polymerase from *sus* F4-*sus* F14-infected bacteria seems to be purified with near-saturating amounts of gp28 since it can be stimulated only 1.2-fold by the addition of purified gp28 (line 3). But, the maximum activity of the phage-modified RNA polymerase in the presence of saturating amounts of gp28 remains significantly less than that obtained with the combination of *B. subtilis* RNA polymerase core and gp28 (compare lines 1 and 3). It is possible that this difference is entirely due to effects introduced during the purification of these enzymes (for example, our preparations of enzyme from phage-infected cells may consistently contain a significant fraction of inactive material). But, the difference of enzyme activity may also reflect a modification of polymerase core after phage infection which affects its interaction with gp28. Such modifications are known to occur after infection with other phages (see ref. 2 for review) but have not yet been detected after phage SP01 infection.

When gp28 is combined with host RNA polymerase core, the reconstructed RNA polymerase has the ability to transcribe 'middle' SP01 genes asymmetrically *in vitro* as shown in Figs 2 and 3.  $^3\text{H}$ -RNA was synthesised for 10 min *in vitro* with excess native SP01 DNA in the presence of 0.04 M  $\text{NH}_4\text{Cl}$  and 0.16 M KCl and was analysed by hybridisation-competition with unlabelled RNA extracted from phage SP01-infected *B. subtilis*. The rationale of this analysis was described previously<sup>15</sup>. Figure 2a compares the

competition patterns of  $^3\text{H}$ -RNA made *in vitro* by *B. subtilis* polymerase core with added purified gp28 and of  $^3\text{H}$ -RNA made by the phage-modified RNA polymerase isolated with bound gp28. The similarity of these two *in vitro* synthesised RNA samples is obvious. Both are composed mainly of middle RNA transcripts as judged by the following criteria: (1) poor competition by *in vivo* early RNA; (2) maximum competition when *in vivo* middle RNA is

**Fig. 2** Hybridisation-competition analysis of SP01  $^3\text{H}$ -RNA synthesised *in vitro* with *B. subtilis* RNA polymerase core in absence or presence of gp28.  $^3\text{H}$ -RNA was prepared by first combining the following components in sequence on ice in 240  $\mu\text{l}$ : 50  $\mu\text{l}$  of gp28 in buffer G containing 0.2 M  $\text{NH}_4\text{Cl}$  and 25% (v/v) glycerol or 50  $\mu\text{l}$  of the same solution without gp28, 1  $\mu\text{g}$  of *B. subtilis* RNA polymerase core, 10  $\mu\text{g}$  of SP01 DNA, 1 mM each of ATP, GTP and CTP, 0.12 mM  $^3\text{H}$ -UTP (560 c.p.m.  $\text{pmol}^{-1}$ ), 0.1 M Tris-HCl, pH 8, 0.1 mM each of EDTA and dithiothreitol, 0.8 mM spermidine, 0.16 M KCl. The sample was incubated for 5 min at 30  $^{\circ}\text{C}$ , and then was made 0.01 M  $\text{MgCl}_2$  by addition of 10  $\mu\text{l}$  of 0.25 M  $\text{MgCl}_2$ . After 10 min, 25  $\mu\text{l}$  of 0.2 M EDTA and 0.2% SDS was added to stop the reaction. Synthesis of  $^3\text{H}$ -RNA by RNA polymerase from *B. subtilis* infected for 10 min with *sus* F4-*sus* F14 double mutant of SP01 phage was essentially the same except for the following changes: the final volume was 200  $\mu\text{l}$  containing 7.2  $\mu\text{g}$  SP01 DNA, 0.2 M KCl, and 0.1 mM  $^3\text{H}$ -UTP (750 c.p.m.  $\text{pmol}^{-1}$ ). The  $^3\text{H}$ -RNA was extracted with phenol and prepared for analysis as described elsewhere<sup>16</sup>. The conditions of RNA synthesis used here differ from those which we used previously<sup>3,6</sup> and resemble those of Losick and Pero<sup>18</sup>. We have previously assayed asymmetry of transcription at lower ionic strength, while limiting RNA synthesis to promoter-proximal segments of RNA<sup>3,6</sup>. Losick and Pero<sup>18</sup> showed *in vitro* asymmetrical transcription by modified polymerases at higher ionic strength during relatively long periods of synthesis. We compared both procedures with the phage-modified RNA polymerase B-P and found similar degrees of asymmetry as measured by RNA-RNA duplex formation. We used the conditions specified here because they yield more RNA for a given quantity of gp28. Hybridisation of the  $^3\text{H}$ -RNA (0.02  $\mu\text{g ml}^{-1}$ ) to SP01 DNA (10  $\mu\text{g ml}^{-1}$ ) was competed against by unlabelled RNA from SP01 infected *B. subtilis*. The aim of the competition experiments is to distinguish early, middle and late viral RNA together with their symmetrical antimesenger counterparts. Each of these three classes of messages is composed of subclasses (see ref. 16). Early (*e* and *em*) RNA is synthesised when infection is in the presence of chloramphenicol (CAM). We collected this RNA 12 min after infection at 37  $^{\circ}\text{C}$ . RNA synthesised after infection with SP01 *sus* F14 (gene 33) phage and collected 12 min after infection contains middle RNA species (*em*, *m* and *m*<sub>1</sub>). Late RNA (*m*<sub>2</sub> and *l*) is collected 28 min after infection with wild type phage. (The mixed competitor sequence used here allows us to neglect questions of transcriptional shut-off *in vivo*.)  $\Delta$ ,  $\blacktriangle$ , Early RNA;  $\circ$ ,  $\bullet$ , middle RNA;  $\square$ ,  $\blacksquare$ , mixed competition of 0.72 mg  $\text{ml}^{-1}$  early RNA with increasing concentrations of middle RNA;  $\diamond$ ,  $\blacklozenge$ , mixed competition of 0.72 mg  $\text{ml}^{-1}$  early RNA, 0.61 mg  $\text{ml}^{-1}$  middle RNA and increasing concentrations of late RNA. *a*,  $^3\text{H}$ -RNA synthesised with RNA polymerase core from uninfected *B. subtilis* with added gp28 (solid line, closed symbols) and  $^3\text{H}$ -RNA synthesised with phage-modified RNA polymerase from *sus* F4-*sus* F14 SP01 infected *B. subtilis* (subunit composition  $\beta$ ,  $\beta'$ ,  $\alpha$ , gp28,  $\omega^1$ ,  $\omega^2$ ; dashed line, open symbols). The input of  $^3\text{H}$ -RNA made with the reconstituted RNA polymerase was 927 c.p.m., and hybridisation in the absence of competing RNA was 972 c.p.m. The radioactivity bound to the filter in the absence of DNA was 14 c.p.m. The input of  $^3\text{H}$ -RNA made with the phage-modified RNA polymerase was 881 c.p.m., and hybridisation in the absence of competing RNA was 579 c.p.m. The radioactivity bound to the filter in the absence of DNA was 30 c.p.m. *b*,  $^3\text{H}$ -RNA synthesised with RNA polymerase core from uninfected *B. subtilis*. Input radioactivity was 555 c.p.m. per assay and hybridisation in the absence of competing RNA was 494 c.p.m. The radioactivity bound to the filter in the absence of DNA was 14 c.p.m.

**Table 1** Activity and template selectivity of RNA polymerase reconstituted from purified gp28 and *B. subtilis* RNA polymerase core

RNA polymerase	DNA	c.p.m.	
		(-)gp28	(+)gp28
1 <i>B. subtilis</i> core	SP01	811	3,458
2 <i>B. subtilis</i> core	$\phi$ 29	58	99
3 <i>sus</i> F4- <i>sus</i> F14	SP01	1,976	2,371
4 <i>sus</i> F4- <i>sus</i> F14	$\phi$ 29	93	—

The following components were first combined in sequence on ice: 5  $\mu\text{l}$  of gp28 in buffer G with 25% (v/v) glycerol and 0.2 M  $\text{NH}_4\text{Cl}$  or 5  $\mu\text{l}$  of buffer alone, 0.1  $\mu\text{g}$  RNA polymerase in 25  $\mu\text{l}$  of TGB, 1  $\mu\text{g}$  of DNA in 10  $\mu\text{l}$  0.01 M Tris-HCl, pH 7.5, 0.001 M EDTA, 50  $\mu\text{l}$  of reaction components to give 90  $\mu\text{l}$  containing 0.11 M Tris-HCl, pH 8, 0.11 mM each of EDTA and dithiothreitol, 0.88 mM spermidine chloride, 1.1 mM each of ATP, GTP, CTP, and 0.13 mM  $^3\text{H}$ -UTP (100 c.p.m.  $\text{pmol}^{-1}$ ). After a 5 min incubation at 30  $^{\circ}\text{C}$ , the reaction was started by adding 10  $\mu\text{l}$  of 0.1 M  $\text{MgCl}_2$ . After a further 5 min the reaction was stopped and incorporation of  $^3\text{H}$ -UTP into acid insoluble material was measured as described previously<sup>3</sup>. Incorporation for 0.1  $\mu\text{g}$  RNA polymerase holoenzyme from uninfected *B. subtilis* was 4,501 c.p.m. in the presence of SP01 DNA and 3,887 c.p.m. in the presence of  $\phi$ 29 DNA. Incorporation in the absence of RNA polymerase core and in the presence of gp28 was 24 c.p.m.

added to early RNA; and (3) poor competition by added *in vivo* late RNA. The hybridisation-competition pattern of RNA synthesised *in vitro* with *B. subtilis* RNA polymerase core alone (Fig. 2b) is distinctly different in that all the *in vivo* RNA's compete to some extent, but poorly. The qualitative effect that gp28 has on the composition of  $^3\text{H}$ -RNA made *in vitro* is most strikingly evident when the asymmetry of the *in vitro*-synthesised RNA is assayed in terms of the ability to form RNase-resistant RNA-RNA duplexes with early, middle and late *in vivo* RNA. Figure 3 shows that the  $^3\text{H}$ -RNA made by RNA polymerase core alone is symmetrical (see further comments below). In contrast, the  $^3\text{H}$ -RNA made with RNA polymerase core in the presence of added gp28 is relatively asymmetrical. More specifically, the mixed competitor assays for hybridisation-competition and the mixed RNA assays for RNA-RNA duplex formation (Figs 2 and 3) provide the following conclusions: that while the minor component of transcription from early genes is relatively symmetrical, the major component of middle RNA is almost perfectly asymmetrical. The pattern of RNA-RNA duplex formation by the RNA made with RNA polymerase from *sus* F4-*sus* F14 SP01 phage infected *B. subtilis* is identical to that for RNA made with RNA polymerase core and gp28.

Some comment on the symmetry of the SP01 RNA synthesised with *B. subtilis* core enzyme is appropriate. The data shown here imply that a slight excess of anti-messenger is synthesised (57% duplex at the highest concentration of all RNAs used, after subtracting background). This is approximately the value previously obtained in somewhat different conditions of transcription<sup>3</sup>. Approximately equal hybridisation of *in vitro* RNA to complementary DNA strands is often interpreted as indicating random transcription of helical SP01 DNA by core enzyme. While asymmetry of RNA synthesis is an excellent indication of selectivity of transcription, the reverse inference is not valid. There is as yet no clear evidence that initiation by any prokaryotic RNA polymerase core enzyme on any continuous natural DNA template is random (that is, able to use any pyrimidine nucleotide in DNA to signal initiation). Our finding of a slight excess of antimessenger synthesised by RNA polymerase core is consistent with at least partially selective transcription. This selectivity clearly generates a collection of transcripts that are very different from *in vivo* RNA and from the transcripts generated by the fidelity of the complete transcriptases. The observed selectivity of transcription by *B. subtilis* RNA polymerase core could arise at the level of initiation or at termination.

## Discussion

Thus, gp28, through its binding to RNA polymerase, is responsible for directing the asymmetrical synthesis of middle SP01 RNA *in vitro*. We surmise that gp28 confers on RNA polymerase core the template-specific ability to form rapid initiation complexes with SP01 DNA which we previously demonstrated to be a property of the phage-modified RNA polymerase<sup>8</sup>. How do these properties of RNA polymerase relate to the regulation of phage SP01 transcription? Fujita *et al.*<sup>11</sup> presented a model for the regulation of SP01 transcription based on an analysis of RNA synthesis during phage development<sup>16</sup> and on the properties of SP01 mutations which affect viral transcription. The model, in its simplest form, involved a positive effector for the initiation of middle SP01 transcription, a positive effector composed of two proteins, for late SP01 RNA synthesis and a single negative element for the repression of a class of middle SP01 RNA. The products of two genes (33 and 34) which regulate the appearance of late classes of SP01 RNA have been shown to be RNA polymerase-binding proteins<sup>12</sup>. When added to *B. subtilis* RNA polymerase core, these two subunits act synergistically to promote late SP01 RNA synthesis *in vitro*<sup>13</sup>. These results combined with our observations and those of Fox *et al.*<sup>10</sup>, identify the three RNA-polymerase binding proteins as two of the positive effectors proposed by Fujita *et al.*<sup>11</sup>.

Although virus-coded proteins which bind to host RNA polymerase have been described<sup>1,2</sup>, only those regulating SP01

**Fig. 3** RNA-RNA duplexes between *in vivo* RNA and  $^3\text{H}$ -RNA synthesised *in vitro* with *B. subtilis* RNA polymerase core in the absence or presence of gp28 and  $^3\text{H}$ -RNA synthesised with phage-modified RNA polymerase from *sus* F4-*sus* F14 SP01 infected *B. subtilis*. The  $^3\text{H}$ -RNA analysed by hybridisation-competition in Fig. 2a and b was assayed for the formation of RNA-RNA duplexes with *in vivo* RNA from SP01 infected bacteria as described elsewhere<sup>6,19</sup>. Each sample contained approximately  $0.02 \mu\text{g ml}^{-1}$   $^3\text{H}$ -RNA. For  $^3\text{H}$ -RNA synthesised by modified RNA polymerase from *B. subtilis* infected with SP01 *sus* F4-*sus* F14 (cross-hatched symbols; dashed line) and by polymerase core in the absence (filled symbols) or the presence of gp28 (open symbols) input radioactivity was 881 c.p.m., 555 c.p.m. and 927 c.p.m., respectively. The  $^3\text{H}$ -RNA was annealed to increasing concentrations of early RNA ( $\Delta$ , cross-hatched triangle,  $\blacktriangle$ ), 0.90  $\text{mg ml}^{-1}$  early RNA and increasing concentration of middle RNA ( $\square$ , cross-hatched square,  $\blacksquare$ ), and 0.90  $\text{mg ml}^{-1}$  early RNA, 0.80  $\text{mg ml}^{-1}$  middle RNA with increasing concentrations of late RNA ( $\diamond$ , cross-hatched diamond,  $\blacklozenge$ ).

development have up till now been amenable to *in vitro* analysis of selective transcription. The availability of these SP01-coded subunits should allow a closer study of the means by which they exert their regulatory influence. It may now be possible to study, *in vitro*, the dynamic interaction of these effectors with bacterial  $\sigma$  factor and with RNA polymerase core and, in that way, to understand whether these interactions alone can generate the major transitions of transcription that characterise gene expression during phage SP01 development. Models generated by such an investigation may relate to other developmental processes, at least in prokaryotes.

# Endogenous inhibitor of prostaglandin synthetase

S. A. Saeed, Wendy J. McDonald-Gibson, Josephine Cuthbert, Julia L. Copas, C. Schneider\*, P. J. Gardiner, N. M. Butt & H. O. J. Collier

Research Department, Miles Laboratories Limited, Stoke Poges, Slough, UK

*Mammalian serum and plasma contain an endogenous inhibitor of prostaglandin synthetase (EIPS). Human plasma fractions rich in EIPS show anti-inflammatory activity in vivo. In rats, glucocorticoids raise EIPS activity of plasma and serum. These findings suggest the existence of a natural mechanism of controlling prostaglandin synthesis, possibly related to corticosteroid action.*

PROSTAGLANDINS (PGs) can elicit or intensify various unpleasant effects such as vomiting, diarrhoea, cough, pain and inflammation. Although PGs may well have an underlying defensive function, their production can at times be excessive and harmful<sup>1</sup>. There seems, therefore, to be a need to control PG levels in tissues. It is known that these levels can be controlled through the availability of substrate for PG synthetase or the activity of enzymes metabolising prostaglandins. We describe here a new, direct endogenous mechanism of inhibiting PG synthesis that could also contribute to the control of PG levels. This was brought to light by the observation (by S.A.S.) that human serum potentially inhibited the conversion of arachidonic acid into PGE<sub>2</sub> and PGF<sub>2α</sub> by homogenate of bull seminal vesicles (BSV). Serum and plasma of other mammals also possess this property. In human plasma, this property was associated with a particular fraction, the activity of which could be increased by further fractionation. This and other evidence indicated the presence of an endogenous inhibitor of prostaglandin synthetase (EIPS). We outline below experiments on the occurrence of EIPS, on its biochemical and pharmacological properties and on its possible relationship to the mechanism of action of anti-inflammatory steroids.

## Inhibition of PG synthesis by mammalian serum and plasma

Two methods were used for measuring the extent of PG synthesis *in vitro*. First, arachidonic acid was incubated with bovine seminal vesicle homogenate and the PGs formed were either estimated as total PG-like activity on rat or hamster stomach fundus or separated by thin-layer chromatography (TLC) and estimated as PGE<sub>2</sub> on these tissues or as PGF<sub>2α</sub> on rat colon, as previously described<sup>2</sup>. Second, tritiated arachidonic acid was incubated with bovine seminal vesicle homogenate, the PGE<sub>2</sub> and PGF<sub>2α</sub> formed were separated by TLC and estimated by liquid scintillation spectrometry. Further details of both methods are given in Tables 1 and 2.

Table 1 illustrates the concentration-response relationships for inhibition of total PG synthesis by several vertebrate sera. Except chicken, which was inactive, these sera, at concentrations of 25% v/v or less, inhibited PG production by 70% or

more. These effects were concentration-related ( $P < 0.05$  for slopes of concentration-response lines). The mean values with standard error for percentage concentration (v/v) to inhibit PG production by 50% (IC<sub>50</sub>) of the sera tested were: rat,  $1.11 \pm 0.21\%$ ; human,  $1.37 \pm 0.55\%$ ; dog,  $2.96 \pm 0.3\%$ ; rabbit,  $7.50 \pm 1.35\%$ ; mare,  $9.30 \pm 0.41\%$ .

In a few experiments, sera of guinea pig, ox and foetal calf were also tested. Guinea pig and ox sera inhibited PG synthesis at dilutions comparable with those in Table 1, but foetal calf serum was ineffective. Inhibitory activity was also found in time-expired human citrated plasma from a blood bank and in fresh rat plasma containing  $0.2 \text{ mg ml}^{-1}$  of disodium EDTA. When incubated in the standard test conditions with BSV homogenate, the IC<sub>50</sub> values of the citrated human plasma and fresh rat plasma were  $0.78 \pm 0.06\%$  v/v and  $1.74 \pm 0.19\%$  v/v respectively.

**Fig. 1** Time course of inhibition by human serum or aspirin of PG synthesis by bovine seminal vesicle homogenate; ●, 0.5% serum v/v; ○, 5.0% serum v/v; ▲, 0.625 mM aspirin; and △, 3.13 mM aspirin. Incubations were conducted for 1, 5, 15 and 30 min. Values are the means of three experiments. Other details as in Table 1.

Table 1 Inhibition of prostaglandin synthesis by sera

Serum concentration (%v/v)	Rat	Human	Inhibition of total PG production (%) Dog	Rabbit	Mare	Chicken
0.05	NT	13.7±5.8	NT	NT	NT	NT
0.5	27.7±4.91	34.7±13.7	14.0±4.5	2.1±1.2	15.0±9.0	NA
2.5	65.6±8.56	NT	NT	NT	NT	NT
5.0	93.3±2.14	88.7±2.2	61.0±2.1	16.8±9.0	25.0±3.0	NA
25.0	NT	90.0±3.5	97.7±0.38	91.5±0.9	91.0±1.0	NA

Inhibition values are mean  $\pm$  s.e.m. NA, not active; NT, not tested. Inhibition, by pooled serum from each species, of PG production was measured in a standard assay mixture (2 ml), containing 50 mM phosphate buffer, 0.25 ml Na<sub>2</sub>EDTA, 1.3 mM reduced glutathione, 0.5 ml bovine seminal vesicle homogenate, and an appropriate volume of the test serum or of isotonic saline as control<sup>2</sup>. The reaction was started by the addition of sodium arachidonate (final concentration 61  $\mu$ M) and the tubes aerated at 37 °C with gentle shaking. After 15 min, 2 ml of 0.2 M citric acid and 16 ml ethylacetate were added to stop the reaction. After mixing and centrifugation for 5 min at 600g, 10 ml of the ethylacetate layer was evaporated to dryness, the residue was redissolved in Krebs solution and PG-like activity of the samples assayed on rat or hamster<sup>3</sup> fundus, using PGE<sub>2</sub> as reference.

In some experiments, the PGE<sub>2</sub> and PGF<sub>2 $\alpha$</sub>  produced by bovine seminal vesicle homogenate in the presence of various concentrations of human serum and in its absence, were separated by TLC using the AI solvent system, and assayed on rat fundus and rat colon respectively. Human serum, at 0.5, 5 and 25% v/v, inhibited production of PGE<sub>2</sub> by 29.7±14.9, 88.7±5.8 and 96.5±3.2% respectively. The serum at these concentrations inhibited PGF<sub>2 $\alpha$</sub>  production by 58.0±17.1, 78.7±3.9 and 73.7±2.4% respectively. That the slope of the concentration-response line for PGF<sub>2 $\alpha$</sub>  was not significant may be attributed to the high standard error of the estimate at 0.5% serum. In the experiments described below with labelled arachidonic acid and a purified fraction of human plasma, the slopes of the concentration-response lines were all significant ( $P < 0.005$ , Table 2).

The time course of inhibition of PG synthesis by human serum was compared with that of aspirin, using two concentrations of each inhibitor (Fig. 1). Human serum exerted its maximal effect between 1 and 5 min and aspirin did so between 10 and 15 min after the start of incubation.

To eliminate the possibility that these inhibitory effects might largely be due to increased prostaglandin breakdown by the test serum, we studied the effect of the most potent serum tested (rat) on the main product of PG synthesis by bovine seminal vesicle homogenate (PGE<sub>2</sub>) in our experimental conditions. In two experiments, 0.25  $\mu$ Ci of <sup>3</sup>H-PGE<sub>2</sub> (specific activity, 140 Ci per mmol) was incubated with 0.5, 5.0 or 15.0% v/v rat serum for 15 min. The reaction was stopped with citric acid, prostaglandins were extracted with ethylacetate and separated by TLC in a modified AI system<sup>2</sup>. Areas corresponding to reference prostaglandins were scraped into scintillation vials and radioactivity in disintegrations per min estimated by liquid scintillation spectrometry. In the two experiments, percentage losses of tritiated PGE<sub>2</sub> were respectively:

0.5% serum, 0 and 30; 5% serum, 6 and 30; 15% serum, 0 and 26. In further experiments using the above conditions, the effect of various concentrations of a purified EIPS fraction of human plasma (purified Cohn IV-4, Table 2) instead of rat serum, on <sup>3</sup>H-PGE<sub>2</sub> and <sup>3</sup>H-PGF<sub>2 $\alpha$</sub>  (specific activity 15 Ci mmol<sup>-1</sup>) was investigated. In two experiments, percentage losses of tritiated PGE<sub>2</sub> were respectively: 50  $\mu$ g ml<sup>-1</sup> EIPS fraction, 0 and 2.4; 200  $\mu$ g ml<sup>-1</sup> EIPS fraction, 13.1 and 8.4; 500  $\mu$ g ml<sup>-1</sup> EIPS fraction 0 and 7.0. In similar experimental conditions, no loss of added <sup>3</sup>H-PGF<sub>2 $\alpha$</sub>  occurred. On the basis of these results we therefore concluded that the decrease in net production of prostaglandins in the presence of rat serum and purified EIPS fraction could mainly be attributed to the inhibition of PG synthesis rather than to activation of PG degradation.

### Activity of human plasma fractions

The ability of partially purified Cohn fractions I to VI of human plasma to inhibit PG synthesis by BSV was tested. Fractions I, II, III, V and VI were inactive at 1,500  $\mu$ g ml<sup>-1</sup> or lower concentrations; but fraction IV ( $\alpha$ -globulins) was active at 50, 500 and 1,500  $\mu$ g ml<sup>-1</sup>. Subfractions 1 and 4 of fraction IV, which were available, were then tested at 5–1,500  $\mu$ g ml<sup>-1</sup> (Table 2). Subfraction 4 was considerably more active than subfraction 1 and was, therefore, further purified (Table 2). This purified material and various specimens of Cohn IV-4 were therefore used in the pharmacological tests described below.

### Inhibition of adjuvant arthritis

As known inhibitors of PG synthetase ameliorate adjuvant arthritis in the rat<sup>4,5</sup>, we tested Cohn subfraction IV-4 against the swelling of the hind feet of rats that had received an intraplantar injection of Freund's adjuvant. Treatment with Cohn IV-4 lessened the extent of both the intense swelling of the

Table 2 Inhibitory activity of human plasma Cohn fractions IV, IV-1, IV-4 and purified IV-4 against PG synthesis

Concentration ( $\mu$ g ml <sup>-1</sup> )	Inhibition by (%)			Purified IV-4

1,500	77.3±3.2	39.4±0.96	73.0±1.8	NT	NT	NT	NT

Inhibition values are mean  $\pm$  s.e.m. Human plasma Cohn fractions IV, IV-1 and IV-4 were from Miles Laboratories. Purification of Cohn IV-4 was carried out by precipitation with 50% saturated ammonium sulphate, followed by chromatography on DEAE-cellulose, using a linear gradient of sodium acetate buffer (pH 5.0) from 0.01 to 0.5 M. Experiments with Cohn IV, IV-1 and IV-4 were performed using bioassay of total PG-like substances produced by incubating arachidonic acid with bovine seminal vesicle homogenate, as in Table 1. Experiments with purified Cohn IV-4 were performed using <sup>3</sup>H-arachidonic acid (specific activity 80 Ci mmol<sup>-1</sup>) and bovine seminal vesicle homogenate. The incubation mixtures, consisting of 1  $\mu$ Ci <sup>3</sup>H-sodium arachidonate (0.061 mM), reduced glutathione or noradrenaline, 0.5 ml bovine seminal vesicle homogenate and purified Cohn IV-4 as indicated, in 2 ml of 50 mM phosphate buffer (pH 7.4) were incubated in glass tubes at 37 °C for 15 min with gentle shaking. The reaction was stopped by adding 2 ml 0.2 M citric acid and 16 ml ethylacetate, and 100  $\mu$ g of unlabelled PGE<sub>2</sub> and PGF<sub>2 $\alpha$</sub>  were added as carriers. The radioactivity was quantitatively extracted in the ethylacetate phase, the extracts were evaporated to dryness, taken up in 400  $\mu$ l absolute ethanol and submitted to TLC on silica gel plates in the AI solvent system, with reference PGE<sub>2</sub> and PGF<sub>2 $\alpha$</sub>  as markers. After chromatography, the zones corresponding to PGE<sub>2</sub> and PGF<sub>2 $\alpha$</sub>  were scraped into scintillation vials and eluted with 1 ml ethanol. The radioactivity was determined by scintillation counting in Unisolve 1 (also containing 5 g l<sup>-1</sup> Cab-o-sil). To determine percentage inhibition of PG synthesis, radioactivity in c.p.m. of PGE<sub>2</sub> and PGF<sub>2 $\alpha$</sub>  in zones from test incubates was compared with that of controls.

\*Noradrenaline 1.3 mM used as cofactor instead of 1.3 mM reduced glutathione, which was used in all other incubates.

injected hind foot and the more gradual and less intense swelling of the uninjected foot (Fig. 2). Analysis of results (Mann-Whitney *U* test) on day 13 shows that, in comparison with saline, subfraction IV-4 both at 2 and 10 mg per kg body weight subcutaneously, given 1 d before adjuvant and then daily (except day 4) until day 11, significantly ( $P < 0.05$ ) reduced the swelling of the adjuvant-treated left hind foot and of the untreated right hind foot. The higher dose (10 mg per kg) also significantly ( $P < 0.05$ ) reduced the incidence of swelling of the fore feet and totally suppressed the incidence of nodules in the tail ( $P < 0.05$ ).

### Inhibition of bronchoconstriction

In 13 anaesthetised guinea pigs, purified Cohn subfraction IV-4, given intravenously (i.v.) in doses of 5, 20, 50 or 100 mg per kg, inhibited the increase of airway resistance and the decrease of lung compliance induced by i.v. injection of 0.1–0.5 mg per kg of arachidonate (Table 3). At doses effective in inhibiting bronchoconstriction induced by arachidonate, Cohn subfraction IV-4 did not inhibit bronchoconstriction induced by submaximal doses of  $\text{PGF}_{2\alpha}$  or acetylcholine (three guinea pigs).

Like aspirin<sup>6</sup>, indomethacin 33 and 100  $\mu\text{g}$  per kg i.v. inhibited the bronchoconstriction induced by i.v. arachidonate (Table 3), without inhibiting the response to  $\text{PGF}_{2\alpha}$  or acetylcholine.

For two reasons, we also tested the purified fraction of Cohn IV-4 against bradykinin-induced bronchoconstriction in the guinea pig. First, this bronchoconstriction is known to be mainly due to stimulation by bradykinin of prostaglandin production in the lungs<sup>7</sup>. Second, virtually the only drugs that suppress this effect are those that inhibit prostaglandin biosynthesis<sup>8</sup>.

Purified subfraction IV-4 inhibited the effect of intravenous challenge with bradykinin in this preparation (Table 3). In these tests indomethacin was considerably more potent than aspirin, whereas in previous experiments of this type, indomethacin had had unexpectedly low potency compared with aspirin<sup>6</sup>.

In preliminary experiments on human isolated bronchial muscle, prepared as previously described<sup>8</sup>, Cohn subfraction

IV-4, 0.1 and 1.0  $\text{mg ml}^{-1}$ , relaxed the muscle and inhibited the contraction induced by sodium arachidonate, 50  $\mu\text{g ml}^{-1}$ .

### Effect of corticosteroids on EIPS levels

In a preliminary experiment, 56 rats were given intraperitoneal (i.p.) dexamethasone sodium phosphate (0.1, 0.8 or 6 mg per kg); 4, 24, 48 and 72 h later rats were killed in groups of four or five, and the pooled serum of each group was tested for inhibitory activity. Dexamethasone raised, in a dose-related way, the ability of the serum to inhibit PG synthesis. This effect was apparent at 24 h after treatment, it reached a peak at 48 h and was considerably diminished at 72 h. In a similar experiment, using 72 rats, an i.p. dose of hydrocortisone sodium succinate (11, 90 or 360 mg per kg) likewise raised the inhibitory activity of the serum, with a comparable time course. In a third experiment, on 20 rats, aldosterone (0.2 mg per kg) failed to increase the inhibitory activity of the serum over a 72-h period.

In a further experiment on rats, dexamethasone sodium phosphate (24 mg per kg) or hydrocortisone sodium succinate (360 mg per kg) were given i.p. and 4, 24, 48 and 72 h later, animals were killed in groups of five and each bled individually from the dorsal aorta into tubes containing 0.2  $\text{mg ml}^{-1}$  of disodium EDTA as an anticoagulant. The plasma was separated by centrifugation for 15 min at 600*g* and the potency in inhibiting PG synthetase (EIPS level) of each plasma sample determined by the standard test procedure using bovine seminal vesicle homogenate (details as in Table 1). The results obtained showed that both dexamethasone and hydrocortisone raised plasma EIPS levels with comparable time courses (Fig. 3).

### Endogenous inhibitor of PG synthetase

We have presented evidence that incubation of mammalian blood plasma or serum with bovine seminal vesicle homogenate results in a lowered production of prostaglandins. There are several possible ways in which this could occur, but most of these are incompatible with the evidence. The effect cannot be due to inhibition of phospholipase A because (1) EDTA, which inhibits phospholipase-A, is present in the assay medium and (2), an optimal amount of sodium arachidonate was added to the medium. Neither can the effect be due to inhibition of

**Table 3** Inhibition of increased airway resistance and decreased lung compliance induced by sodium arachidonate or bradykinin

Treatment	Dose (mg per kg)	Challenge substance	% Inhibition of response to challenge*	
			Resistance	Compliance
Purified Cohn IV-4	5	Arachidonate sodium	31.8±4.7	24.4±5.3

	0.1		88.5±11.5	86.0±6.0

Male albino guinea pigs (400–600 g, Dunkin Hartley strain) were anaesthetised with pentobarbitone sodium, 60 mg per kg i.p. The trachea was cannulated for artificial ventilation by a Starling pump (5–8 ml at 72 strokes per min) by a Fleisch 0000 pneumotachograph. The difference in pressure across this device was measured with a Grass differential pressure transducer. This gives a flow signal that was fed into a Hewlett-Packard 8816A analogue computer. Transpulmonary pressure (TPP) was measured with another differential pressure transducer via side-arms to the thoracic cavity and the tracheal cannula. The signals for flow and TPP were applied to the analogue computer so that there was approximately 180° phase difference. Dynamic compliance and airway resistance were derived by the computer from the ingoing signals. Drugs were administered intravenously through the external jugular vein. Arachidonic acid, 99% pure from Sigma was given in doses of 0.1–0.5 mg per kg as the sodium salt. Bradykinin as triacetate from Sigma was given at 1–5  $\mu\text{g}$  per kg. Test drugs were injected 45 s before challenge. Other details as in Table 2.

\*Values are mean ± s.e.m.

Fig. 2 Inhibition by Cohn subfraction IV-4 of adjuvant arthritis in the rat, induced by the method of Newbould<sup>4</sup>. A suspension of 25  $\mu$ g of killed, ground *Mycobacterium butyricum* (Difco) in 50  $\mu$ l of light liquid paraffin was injected into the plantar surface of the left hind foot of each of three groups of 12 rats on day 0 (arrow). On days -1 to 3 and days 5 to 11, saline (■) or subfraction IV-4, 2 mg per kg (▲) or 10 mg per kg (◆) was injected subcutaneously. Foot swelling was measured daily by micrometer, placed sagittally. Closed symbols, injected foot; open symbols, uninjected foot. \*,  $P < 0.05$  for difference of test from saline-treated controls (Mann-Whitney  $U$  test).

PG release from intact cells, because the cells of bovine seminal vesicle homogenate have already been disrupted. The experiments with tritiated  $PGE_2$  and  $PGF_{2\alpha}$  eliminate the possibility that the effect of serum and a purified fraction of plasma rich in EIPS activity was due to activation of enzymes destroying prostaglandins. We conclude that mammalian blood plasma and serum contain a mechanism for inhibiting PG synthetase. The presence of this mechanism in plasma indicates that it is not simply an artefact generated in serum during blood clotting. Since PG synthesis can be inhibited by antioxidants<sup>9,10</sup>, one of which (propyl gallate) has anti-inflammatory activity *in vivo*<sup>10</sup> and since macromolecules and macromolecular complexes have an undoubted, though little-understood, capacity to act as free radical stabilisers<sup>11,12</sup>, we have considered the possibility that the inhibitory effect might be a nonspecific property of blood proteins. This possibility was eliminated by the finding that this effect of plasma was restricted to the  $\alpha$ -globulin fraction, representing about 5% of total plasma proteins. We therefore postulate that plasma and serum contain an endogenous factor (or factors) that potently inhibits PG synthetase (EIPS). Analysis of its biochemical properties showed EIPS to be a protein, because neither deproteinised plasma nor serum inhibited PG synthesis and because EIPS was inactivated by Pronase. EIPS could not be dialysed through a Cellophane membrane, indicating a large molecular size. Further characterisation of human plasma EIPS has shown that its activity is associated with haptoglobins (in preparation). Smith *et al.*<sup>13</sup> have previously described an anti-inflammatory fraction of human plasma. This differs in two main ways from EIPS, however. First, this fraction does not inhibit prostaglandin synthesis; second, it is of relatively low molecular weight (about 1,000).

These observations raise the question: does EIPS represent a natural mechanism for control of PG synthesis? If so, how is EIPS inactivated when a need for PG synthesis arises? If so, again, what is the relevance of EIPS to diseases associated with excessive or unbalanced PG production?

### Anti-inflammatory drugs

By analogy with morphine, which may be regarded as a mimic of an endogenous ligand of the opiate receptor<sup>14,15</sup>, the possibility arises that non-steroidal anti-inflammatory drugs, which inhibit PG synthetase, may act as mimics of EIPS. Other relationships between these drugs and EIPS are possible, however.

Several studies have shown that corticosteroids interfere with the release or production of prostaglandins or related substances in preparations that include human skin homogenate<sup>16</sup>, dog hind leg<sup>17</sup>, adipose tissue<sup>18</sup>, mesenteric artery<sup>19</sup>, cultured synovial cells<sup>20,21</sup>, cultured fibrosarcoma cells<sup>22</sup>, and isolated guinea-pig lungs in anaphylaxis<sup>23</sup>. In most of these studies the mechanism by which corticosteroids acted was not fully identified; but Nijkamp *et al.*<sup>23</sup> showed that corticosteroids, with a relative potency comparable to their anti-inflammatory activity *in vivo*, interfere with the release of arachidonate, induced by rabbit aorta contracting substance-releasing factor (RCS-RF).

Fig. 3 Changes in EIPS levels of blood plasma taken from rats at various times after the intraperitoneal injection of dexamethasone or hydrocortisone. Cross-hatched column, 360 mg per kg hydrocortisone sodium succinate; stippled column, 24 mg per kg dexamethasone sodium phosphate. Each column represents the mean  $\pm$  s.e.m. of five determinations. For other details see text and Table 1. \*,  $P < 0.05$ ; \*\*,  $P < 0.025$ ; \*\*\*,  $P < 0.0005$  for difference from saline-treated controls (Student's  $t$  test).

In the experiments described here we have shown that, in normal rats, administration of a natural or a synthetic anti-inflammatory glucocorticoid (hydrocortisone or dexamethasone), but not of the mineralocorticoid, aldosterone, increased the ability of the plasma or serum to inhibit prostaglandin synthesis by bull seminal vesicle homogenate. This effect is presumably due to the increase of EIPS. This suggests that glucocorticoids may act, at least in part, by increasing EIPS.

## A search for the reported 400-keV $\gamma$ -ray line from Crab Nebula

LEVENTHAL *et al.*<sup>1</sup> have reported a possible  $\gamma$ -ray line at  $400 \pm 1$  keV from the Crab Nebula. The measurement was achieved with a balloon-borne high resolution  $\gamma$ -ray telescope flown from Alamogordo, New Mexico on 10–11 May 1976. The intensity and the width of the line are reported to be  $(2.24 \pm 0.65) \times 10^{-3}$  photon  $\text{cm}^{-2} \text{s}^{-1}$  and  $\lesssim 3$  KeV, respectively. These authors suggested that a possible origin of this line may be the gravitational redshift of the 0.511 MeV annihilation line produced near the surface of the neutron star. The line, if real, is of great astrophysical interest, and a confirmation of the measurement is therefore important. We report here the results of our search for this feature.

On 10 June 1974 we conducted a balloon experiment over Palestine, Texas with a large volume high resolution  $\gamma$ -ray spectrometer. The instrument which has been described previously<sup>2</sup> consisted of four 40-cm<sup>3</sup> Ge(Li) crystals (only three were operational for the flight) operating in the energy range of 0.06–10 MeV. This cluster of detectors is surrounded by a CsI(Na) anticoincidence shield for reducing the background and providing collimation of 25° FWHM at 400 keV. The total effective area (efficiency  $\times$  front area) is 10.4 cm<sup>2</sup> and the energy resolution is 2.2 keV FWHM at the same energy. The objectives of the experiment were to measure (1) X-ray and  $\gamma$ -ray emissions from the Crab Nebula, (2) diffuse cosmic fluxes (3) atmospheric  $\gamma$  rays and (4) the instrument's background in a space environment. A study of the 0.511 MeV  $\gamma$  rays from the terrestrial and extraterrestrial environments, results of the observation of a 'flare-like'  $\gamma$ -ray line event, and the hard X-ray spectrum (53–300 keV) of the Crab Nebula are reported elsewhere<sup>3–5</sup>. A detailed analysis of the  $\gamma$ -ray spectrum (0.3–10 MeV) of the Crab Nebula apart from the 400 keV and 511 keV lines is now underway, and will be reported in the future.

The balloon was launched at 1204 UT and reached a float altitude of 2.9 g cm<sup>-2</sup> at approximately 1530 UT where it remained for 6.5 h before shutdown. During the entire flight, the azimuth servo system maintained the instrument's

aperture in a southerly direction and the elevation was set 10° from the zenith, allowing the Crab Nebula and the Sun, separated by 4°, to transit directly through the field of view. Since the viewing axis azimuth and zenith angles were fixed, background variations which may be associated with changes in these parameters by pointing the instrument towards and away from the target such as the method used by Leventhal *et al.*<sup>1</sup> are therefore eliminated. Background variations owing to the balloon spatial drifts are estimated to be  $\sim 1\%$ . Figure 1 shows the time history of the counting rate measured by the three Ge(Li) detectors in the range 65–100 keV. During the first part of float, the aperture was blocked with a 20.3 cm diameter  $\times$  10.2 cm thick NaI(Tl) crystal also in anticoincidence with the prime sensors and the rate decreased from 1.6 counts per s to 0.9 counts per s. The difference can be attributed to  $\gamma$  rays originating from the atmospheric and diffuse cosmic components and entering through the aperture. The Sun and the Crab Nebula transited through the field of view at 1845 UT and 1902 UT, respectively. By 1902 UT the rate had increased to 27% over

Fig. 1 Time history of the counting rate measured by three of the four Ge(Li) detectors (65–100 keV). During the first part of float at 2.9 g cm<sup>-2</sup>, the aperture was covered by a 20.3 cm diameter  $\times$  10.2 cm thick NaI(Tl) detector and the rate decreased from 1.6 to 0.9 counts per s. The difference can be attributed to aperture fluxes which consist of the atmospheric and diffuse cosmic X-rays. The Crab Nebula transited directly over the field of view at 1902 UT.

**Fig. 2** Energy loss spectra. Our measured rates around 400 keV (a) are compared with those reported by Leventhal *et al.*<sup>1</sup> during live-time intervals of 7,113-s (Crab target) and 7,084-s (Crab background), respectively (C. J. MacCallum, personal communication). Their measured line flux of  $2.24 \times 10^{-3}$  photons  $\text{cm}^{-2} \text{s}^{-1}$  should increase our measured rate in the 398–403 keV bin of the Crab plus Background spectrum by  $1.26 \times 10^{-2}$  counts per s. Such an increase of  $3.9\sigma$  statistical significance is not observed in our data. In a +, Crab plus background, 104 min;  $\diamond$ , background, 128 min.

the background measured before and after the transits. Since the Solar Geological data (No. 360–Part 1, 1974) indicated no significant X-ray and  $\gamma$ -ray activity during this period, contributions to the enhancement of the measured rate from the Sun are expected to be negligible.

Figure 2a shows two energy-loss spectra in the range 388–412 keV with one of the spectra accumulated over a 104 min (1812–1956 UT) live-time interval during the Crab Nebula transit and the other over a 128 min live-time interval before (1702–1742 UT) and after (2016–2148 UT) the transit. The length of the source transit-interval selected for analysis was chosen such that the ratio of the total number of counts from the Crab Nebula over its statistical significance was maximised. The net average exposed effective area of the instrument to the Crab Nebula during the transit was  $5.62 \text{ cm}^2$  at 400 keV. This value is determined experimentally using laboratory radioactive sources and computation with the Monte Carlo technique<sup>3,6</sup> and further corrected for effects of attenuation of the overlying atmosphere and materials in the gondola, balloon spatial drift<sup>3</sup> and leakages through the shield. Also shown in Fig. 2 for comparison are the corresponding spectra measured by Leventhal *et al.*<sup>1</sup> (C. J. MacCallum, personal communication). During the Crab Nebula transit the difference in our data of the counting rate measured in the 398–403 keV bin and the average rate measured in the two adjacent bins 388–398 keV and 403–413 keV is  $(-2.85 \pm 3.27) \times 10^{-3}$  counts per s. The null result is different from the measurement of Leventhal *et al.* of a positive increase of  $4.0\sigma$  significance using the same bin selection. Their reported line flux of  $2.24 \times 10^{-3}$  photons per  $\text{cm}^2$  per s from the Crab Nebula would increase our measured rate in the 398–403 keV bin of the Crab plus background spectrum by  $1.26 \times 10^{-2}$  counts per s. Such an increase of  $3.9\sigma$  statistical significance is clearly not observed in our data. In addition, our background spectrum with the Crab Nebula outside the field

of view shows rates in the same three energy bins similar to those accumulated during the source transit. As these results are also consistent with our prediction of background variation of 1% owing to balloon spatial drifts, we may rule out the possible explanation that our null results in observing the 400 keV line is caused by systematic background effects.

In conclusion, we did not observe the 400-keV  $\gamma$ -ray line from the Crab Nebula on 10 June 1974. Our result is in contradiction with Leventhal's measurement if a constant source intensity is assumed. The two observations were separated by 2 yr, however, and we cannot rule out the possibility that the feature may vary with time. Observations with a high resolution instrument may resolve this issue.

We thank G. Culp and L. Jung for assistance in conducting the balloon experiment, R. Bishop for contributions to data reduction, Dr G. Riegler for comments on the manuscript, and the National Scientific Balloon Facility for carrying out the balloon flight. (This research was supported under NASA contract NAS 7-100.)

## Hadronic photoabsorption and pair production in pulsars

THERE are two existing models for the acceleration of positive charged particles near the magnetic polar caps of a pulsar. In the first, the work function for a  $^{56}\text{Fe}$  ion bound in the lattice at the stellar surface is assumed, following exhaustive calculations of Flowers *et al.*<sup>1</sup>, to be too large for the occurrence of ion emission. Electron–positron pairs are created through magnetic conversion of curvature photons<sup>2</sup>; the electrons are accelerated inwards to the stellar surface, and the positrons outwards along open lines of magnetic flux to the light cylinder. In the second, the work function is assumed to be negligible and ion emission limited only by space charge effects. In the corotating frame of reference, all components of the surface electric field are zero and inertial ion acceleration<sup>3–5</sup> occurs. For surface magnetic flux densities  $B \gtrsim 10^{12} \text{ G}$ , we shall attempt to show here that the nature and mode of acceleration of the plasma moving outwards along open magnetic flux lines are determined, not by these processes, but by the occurrence of hadronic photoabsorption reactions in the electromagnetic showers produced by ultra-relativistic electrons incident on the stellar surface. This work was prompted by the comment<sup>4</sup> that magnetic conversion of backward moving photons from these showers may be an important source of pairs. The consequences of hadronic photoabsorption do not seem to have been considered previously. Here, it is shown that photons of the energy necessary for conversion in a magnetic flux density of  $10^{12} \text{ G}$  are emitted with high probability in hadronic photoabsorption reactions, and an equation is obtained for the acceleration potential difference in a one-dimensional model of electron–positron pair creation at the magnetic polar cap. The properties of the accelerated plasma are important owing to its probable

connection with radio emission and with the phenomenon of subpulse drift occurring in certain pulsars (see, for example, refs 6, 7).

Consider a photon emitted, for example, at an angle of  $150^\circ$  to the direction of the primary electron, assumed parallel with  $\mathbf{B}$ . For  $B = 10^{12}$  G, the mean free path for magnetic conversion<sup>8</sup> is in the interval  $1 \leq \lambda \leq 10^4$  cm for photon energy  $\epsilon$  such that  $9 \geq \epsilon \geq 5$  MeV. A photon of these properties would have a negligible probability of creation by purely electromagnetic processes, as shown by the shower distribution function tables of Messel and Crawford<sup>9</sup>.

The transverse momentum of most photons in the shower is  $\lesssim 10 mc$ , defined with respect to  $\mathbf{B}$ , and therefore the properties of the shower should be unchanged by the magnetic flux. From the shower distributions<sup>9</sup> (for air) the photon track length at energies of more than 300 MeV is estimated to be  $1.6 W$  radiation lengths, where  $W$  is the primary electron energy in GeV. For  $W \approx 10^3$  GeV, several photoabsorption reactions would occur per shower. The equilibrium state of matter at the stellar surface would be determined by the formation of light nuclei (with negligible work functions) in the spallation of  $^{56}\text{Fe}$  and their emission from the surface by thermal excitation. At the temperatures and densities considered, fusion and diffusion would seem unimportant. Owing to the spallation and the interaction-induced disorder, the matter would have the characteristics of a glassy solid. However large the  $^{56}\text{Fe}$  work function, the plasma moving outwards must have an ionic component. The charge spectrum of light nuclei accelerated would include  $Z = 3-5$ , normally considered to be present in galactic cosmic rays as a result of the interaction of heavier nuclei with the interstellar medium.

For photon energies below the meson threshold, the most important photoabsorption reaction is the formation of the giant dipole resonance. The cross section, integrated over photon energy from 15 to 30 MeV, is a large fraction of the classical sum rule result<sup>10</sup>,  $60(NZ/A)$  mb MeV. For mass numbers  $A > 40$ , neutron emission is the dominant decay mode of the resonance. Proton emission occurs, but is less probable. Photons with energy in the interval  $5 < \epsilon < 9$  MeV are produced with approximately unit probability in both the further decay of the residual nucleus and the capture of the neutron. The average number of photons from these processes entering the magnetosphere with energy such that their mean free path for magnetic conversion is in the interval  $1 < \lambda < 10^4$  cm can be estimated, from the shower distributions<sup>9</sup>, to be of the order of 1–10 for a primary electron of  $10^3$  GeV. A laboratory measurement of the number and energy spectrum should be possible at the lower energies of existing electron beams.

We later summarise some results for a one-dimensional model of pair creation by this mechanism. It is assumed that acceleration occurs for  $0 < z < z_a$ , where  $z$  is the distance from the stellar surface measured along an open line of magnetic flux at the polar cap, and  $z_a \lesssim 10^4$  cm. In the corotating frame of reference, the potential  $\phi(z)$  satisfies the condition

$$\phi(0) = \left( \frac{\partial \phi}{\partial z} \right)_{z_a} = 0 \quad (1)$$

In units of  $\sigma_0 c$ , where  $\sigma_0$  is the (positive) corotational charge density<sup>11</sup>, the ion current density is  $\alpha_1$ , and the electron-positron current density resulting from magnetic conversion between  $z_0$  and  $z_a$  is  $\alpha_2$ . The lower limit  $z_0 \ll z_a$  represents a maximum photon energy. It is assumed that  $\alpha_1 + \alpha_2 = \alpha \leq 1$ .

The first result obtained is that the mean number of photon conversions per primary electron and unit interval of  $z$  is of the form

$$G(z) \propto z^{-1}, \quad z_0 < z < z_a \quad (2)$$

as a function of  $z$ . This is independent of the photon angular distribution, is exact if the photon energy spectrum is  $f(\epsilon) \propto \epsilon^{-2}$ ,

and is a satisfactory approximation for any reasonable  $f(\epsilon)$ . It is assumed, on the basis of the discussion of the giant dipole resonance, that the form of  $f(\epsilon)$  (though not its scale) is independent of primary electron energy. With this result, the potential  $\phi(z)$  satisfying the boundary conditions (1) can be found from Poisson's equation, assuming all particle velocities equal to  $c$ . The maximum acceleration potential is

$$\phi(z_a) = -2\pi\sigma_0 z_a^2 (1 - \alpha + \alpha_2 / \ln(z_a/z_0)) \quad (3)$$

Following the discussion of hadronic photoabsorption, we assume that the mean number of photon conversions between  $z_0$  and  $z_a$  per electron created at  $z$  and accelerated inwards to the stellar surface is

$$F(z) = C\phi(z), \quad z_0 < z < z_a \\ = 0, \quad z < z_0 \quad (4)$$

where the lower limit  $z_0$  satisfies  $z_0 \ll z_0 \ll z_a$  and  $C$  is a function of this lower limit and of  $B$ . The equation for  $\phi(z_a)$  can be derived from the condition for a time-independent electron-positron current density. It is

$$4\phi(z_a)/\phi(z_0) = \exp(2F(z_a)), \text{ in the limit } \alpha \rightarrow 1 \quad (5)$$

or

$$2\phi(z_a)/\phi(z_0) = \exp(\frac{1}{2}F(z_a)), \quad 1 - \alpha \gg \alpha_2 / \ln(z_a/z_0) \quad (6)$$

The solutions of equations (5) and (6) are insensitive to  $z_0$  and as functions of  $C$  are approximately  $\phi(z_a) \propto C^{-1}$ . We estimate  $-\epsilon\phi(z_a) \approx 10^3$  GeV for  $B = 10^{12}$  G on the basis of the earlier (order of magnitude) discussion of photon production. Thus pair production and the outward flow of positrons may occur through this mechanism rather than the conversion of curvature radiation which would require a small radius of curvature ( $< 10^7$  cm) for the open magnetic flux lines at the stellar surface. Both a laboratory measurement of photon production and a detailed study of the effect of the magnetic flux on shower properties, however, are necessary for quantitative estimates of  $C$  and  $\phi(z_a)$ .

I thank Professors J. Arons and M. A. Ruderman for correspondence on particle acceleration, and Dr T. W. Quirk and M. Staton for helpful discussions.

## A classification scheme for pulsars

WE have already<sup>1</sup> distinguished between three types of pulsars depending upon their mode of formation. Here we discuss some implications of this classification scheme. We suggest the nomenclature types L, S and D for the three types of pulsars. Type S (S for single) consists of pulsars formed as a result of supernova explosions of single stars. Types D and L refer to pulsars which come from massive close binary systems. Pulsars produced by

supernova explosions in and leading to the disruption of the binaries belong to type D (D for disrupted), while the old, rejuvenated neutron stars liberated from binaries by the supernova explosions of the companion stars constitute type L (L for liberated). Type D consists of two subsets; a pulsar belongs to type D<sub>1</sub> if its formation, accompanied by the disruption of the binary, is a result of the supernova explosion of the first (originally the more massive) star; to type D<sub>2</sub>, if a result of the supernova explosion of the second (originally the less massive) star. Thus type D<sub>1</sub> pulsars are associated with OB runaways, while type D<sub>2</sub> pulsars are associated with type L pulsars.

This distinction between the three types of pulsars has two significant implications. First, the age of a type L pulsar is not simply determinable from its spin-down rate. Pulsars in massive close binaries are born in rapid rotation like single pulsars<sup>2</sup>, but slow down rapidly<sup>3</sup>. The neutron star spins up due to mass accretion from the companion star and mass loss from the system<sup>4</sup>. In terms of the concept of spin-down age, the neutron star ages rapidly immediately after its formation but is rejuvenated later. Only if the type L pulsar is spinning as rapidly at the time of the disruption of binary, as it was at the time of its formation, is its spin-down age relevant. For type D pulsars, of course, it is as good a measure of the true age as it is for type S pulsars.

Second, a type L or a type D<sub>2</sub> pulsar cannot be assumed to have always been moving with its present velocity, which is the orbital velocity the pulsar had at the time of the disruption of the binary by the second supernova explosion. Before that the system was moving with the velocity it had acquired as a result of the first supernova explosion. An estimate of the velocity can be made from the galactic *z*-distribution of massive X-ray binaries—a stage reached by the OB binary some 4–5 Myr after the first supernova explosion<sup>5</sup>, which can be assumed to have taken place in the galactic plane. As the average distance of massive X-ray binaries above the galactic plane is  $\sim 90$  pc (ref. 6), we conclude that the centre of mass of the system is accelerated to a *z*-velocity of  $\sim 20$ – $30$  km s<sup>−1</sup> by the first supernova explosion.

Since the time interval between the first and the second supernova explosion is about 5–7 Myr (ref. 5), the binary would have moved a distance 100–200 pc perpendicular to the galactic plane before being disrupted by the second supernova explosion. Thus while type S and type D<sub>1</sub> pulsars are born close to the galactic plane, type D<sub>2</sub> and L pulsars are born at large  $|z|$  values. If, however, the space velocity of the pulsar at the time of the disruption of the progenitor binary had a *z*-component, the present *z*-position of the pulsar could be above or below the *z*-value at which the pulsar was formed. Further, since the space velocities of type L and type D pulsars are typically an order of magnitude larger than the centre of mass velocities of their progenitor binaries, a pulsar could move a substantial distance in the *z*-direction after the disruption of the binary so that although it was formed at a large  $|z|$  value, it could now be close to the galactic plane. It could even have crossed the galactic plane and may now appear on the other side. Thus while a type L or a type D<sub>2</sub> pulsar is born at  $|z| \sim 100$ – $200$  pc, its present distance from the galactic plane would depend upon the magnitude and the sign of the *z*-component of its space velocity and on its age as a single object.

We can now review the galactic *z*-distribution of some pulsars. PSR 1133+16 has a transverse velocity of  $320$  km s<sup>−1</sup> at a height  $z = 150$  pc above the galactic plane<sup>7</sup> and a spin down age of 5 Myr. According to ref. 1 it is a type L pulsar. Two hypotheses can then explain its present *z*-position. (1) The progenitor binary had moved a *z*-distance of about 150 pc between the first and the second supernova explosions so that the pulsar was formed at a height  $\sim 150$  pc above the galactic plane and is now moving parallel to it. In that case its radial velocity should be  $\sim -120$  km s<sup>−1</sup>. (2) Or, the pulsar was born  $\sim 150$  pc below the galactic plane. The orbital plane of the progenitor binary was suitably inclined to the galactic plane to give the liberated pulsar an appropriate *z*-velocity. Some time ago, the pulsar must have crossed the galactic plane and is moving up. A similar explanation holds for PSR2021+51 which has a transverse velocity  $\lesssim 400$  km s<sup>−1</sup> but is only 120 pc above the galactic plane<sup>7</sup>. PSR 0823+26, PSR0834+06 and

PSR1237+25 are respectively 420, 210 and 370 pc above the galactic plane and have transverse velocities 506, 118 and 178 km s<sup>−1</sup> respectively<sup>8</sup>. They are all type L pulsars<sup>1</sup>. They must have been born  $\sim 150$  pc above the galactic plane and are moving up.

PSR1929+10 is located at  $z = -7$  pc and has a velocity  $75$  km s<sup>−1</sup> perpendicular to the galactic plane<sup>7</sup>. Since its velocity is much too small for its status as a type L pulsar<sup>1</sup> it must have a large radial velocity. The present location of the pulsar can be explained if we assume that it was born  $\sim 150$  pc below the galactic plane and is now on its way up. PSR0329+54 has a transverse velocity of  $\lesssim 450$  km s<sup>−1</sup> and is located at  $z = -28$  pc (ref. 7). We have classified it as a type D pulsar<sup>1</sup>. Either it is a type D<sub>1</sub> pulsar born at this *z*-value and is moving parallel to the galactic plane, or, alternatively, it is a type D<sub>2</sub> pulsar which was born at a large *z*-value and has since moved closer to the galactic plane. PSR0950+08 has a transverse velocity of  $50$  km s<sup>−1</sup> at  $z = 71$  pc (ref. 7). Since it is a type D pulsar<sup>1</sup>, it must have a large radial velocity. Further to explain its low *z*-value, in spite of its large age (17 Myr), it must be postulated that the pulsar was born at this *z*-value and is moving parallel to the galactic plane. The Vela pulsar 0833−45 is at a low value of  $z$  ( $-24$  pc) as a young type S pulsar should be. Another type S pulsar, PSR2016+28, is also close to the galactic plane ( $z = -33$  pc)<sup>8</sup>. But since it is very old (59 Myr) it must be moving parallel to the galactic plane. The Crab pulsar is located 200 pc below the galactic plane. Since it is an extremely young type S pulsar<sup>1</sup>, it has not moved much from its place of birth. Therefore its progenitor could not have been an OB star, all of which are confined to the galactic plane. Thus, Crab pulsar must be the result of the supernova explosion of a late type, low mass star.

I thank Dr R. Rajamohan for useful discussions.

## Deuterium enrichment in interstellar HCN and HNC

THE cosmic abundance of deuterium, expressed as the ratio D/H, is thought to be approximately  $2 \times 10^{-5}$  (ref. 1). Observations on deuterium-containing molecules, such as DCN (refs 2,3) and DNC (ref. 4), however, indicate much higher values for the molecular ratios DCN/HCN and DNC/HNC. In the case of DCN this was attributed to chemical enrichment involving equilibria such as<sup>5</sup>

or to other mechanisms<sup>6</sup>. But it is difficult to reconcile the observed enrichment of DNC with any of these suggestions. Here we explore the alternatives and correct previous suggestions about the mechanism of formation of interstellar HCN. We consider conditions appropriate to dense molecular clouds such as that in Ori A or NGC2264 where the visual/ultraviolet optical depth is very high and ionisation is predominantly by cosmic rays.

For such clouds ion-molecule reactions in the gas phase<sup>7,8</sup> seem to account satisfactorily for many of the observations on molecular species and we shall base our discussion on this theme. Reactions on dust grains, especially very small ones, may also

play a significant part<sup>9</sup>. In it, the formation of HCN is attributed to the following reactions:

In the low temperature conditions that prevail in interstellar molecular clouds, however, the N–H bonds will not be disrupted in equation (3) and so it should be written

which would be followed by

Thus the ion–molecule reaction between  $\text{C}^+$  and ammonia leads to HNC rather than HCN. It is often stated that  $\text{H}_2\text{CN}^+$  has the structure  $\text{HCNH}^+$ . While this seems to be the most stable isomer<sup>10</sup> there is no reason to doubt that the other isomers  $\text{H}_2\text{CN}^+$  and  $\text{H}_2\text{NC}^+$  correspond to alternative, locally stable arrangements. Unimolecular rearrangements of these less stable isomers to  $\text{HCNH}^+$  would be exceedingly slow at the temperatures prevailing in molecular clouds.

In place of equations (3) and (4) as the main means of producing HCN, the following scheme seems to be the most plausible

In addition to these processes there is the following rapid isomerisation channel for HNC which, of course, is another process for production of HCN:

Calculations on the relative stability of HCN and HNC (ref. 11) imply that the former is more stable by 0.63 eV and this is supported by some laboratory studies of the equilibrium (ref. 12 and unpublished results) so that the equilibrium ratio HNC/HCN is about  $10^{-30}$  at 100 K. The fact that column densities of HNC comparable to those of HCN have been observed in dark clouds indicates that equilibrium between the two species is not established. This is an important observation because its consequence is that related equilibria involving HNC and HCN in proton exchanges likewise will not be established (they would have to be established at rates much faster than equation (9) which is expected to occur at the Langevin rate and with one of the most abundant ionic species in dark clouds). Also because the equilibrium involving equation (9) has as fast a rate constant and as high concentrations (according to the numerical results of the ion–molecule reaction scheme obtained by Herbst and Klemperer, ref. 7) as any other process considered in discussions of deuterium enrichment through chemical equilibration, it is difficult to sustain such interpretations of molecular deuterium enrichment in dense molecular clouds.

We conclude that the explanation of molecular deuterium enrichments in interstellar HCN and HNC must lie in isotope effects that influence the formation processes rather than equilibria involving HCN or HNC.

In the case of HNC the deuterium is introduced, according to reactions (5) and (6) through  $\text{NH}_2\text{D}$ :

As these competing channels involve the fission of an N–H and N–D bond respectively, a very strong preference for the former is

expected in low temperature conditions owing to the substantially greater zero point energy of an N–H bond (typically the zero-point energy difference is  $\sim 800 \text{ cm}^{-1} \equiv 1,200 \text{ K}$ ). Also a similar preference is expected in the second step

Such preferential decompositions, equations (10) and (12), lead to a DNC/HNC ratio equal to that of  $\text{NH}_2\text{D}/\text{NH}_3$ , that is, to a threefold deuterium enrichment compared with that in ammonia.

The mechanism<sup>7,13</sup> of ammonia production in dense molecular clouds is believed to be

where  $\text{M}^+$  is a readily ionisable heavy atom such as Ca, Mg, Si. The formation of  $\text{NH}_2\text{D}$  therefore originates from processes analogous to equations (14), (15) and (16) involving HD. The effect of zero point energies will again be to lead to preferential retention of deuterium in the product molecular ion so that a given abundance ratio of  $\text{HD}/\text{H}_2$  could yield a ratio  $\text{NH}_2\text{D}/\text{NH}_3 = 3(\text{HD}/\text{H}_2)$ . Overall we might expect an enrichment of DNC/HNC up to three times  $\text{HD}/\text{H}_2$  corresponding to an overall sixfold enrichment of deuterium as compared with that exhibited by the dominant species in the molecular cloud ( $\text{H}_2$ ) and thus of the cloud as a whole.

For HCN we need to consider deuteration of species leading to  $\text{CH}_3^+$  or  $\text{CH}_3$ . In the case of the former the processes<sup>14</sup> are probably

which implies that the  $\text{CHD}^+/\text{CH}_2^+ = \text{HD}/\text{H}_2$  and  $\text{CH}_2\text{D}^+/\text{CH}_3^+ = 2(\text{HD}/\text{H}_2)$ . Thus if equations (18), (19), (8) and (4) show the dominant processes for HCN production we could expect an overall deuterium enrichment of HCN of up to four times that of the cloud as a whole. It is not yet clear what is the main channel of production of  $\text{CH}_3$  but if it involves

analogous to equation (17) then we expect the same degree of enrichment to arise for the equations (7) and (8). Thus in either case the expected enrichment of HCN is less than that for HNC.

If, however, HCN is predominantly produced from HNC according to equation (9) then the enrichment corresponds to that of the  $\text{D}^+/\text{H}^+$  ratio because it is this final step that introduces the proton or deuteron that ends up in the HCN or DCN. For dense clouds it is not obvious that the  $\text{D}^+/\text{H}^+$  ratio will exceed that of the overall deuterium/hydrogen ratio for the cloud and so, to the extent that HCN is produced by HNC, we expect diminished deuterium enrichment for this molecule.

While this implies that a greater enrichment of deuterium will be observed for HNC than for HCN, and this is in keeping with the limited observations so far made, it does not account for the very great enrichments, about 100-fold for HCN, 2,000-fold for HNC so far reported<sup>3,4</sup>. Since it does not seem feasible for any relevant chemical equilibria to be established on the time scales available for dense interstellar clouds we are forced to turn to kinetic isotope effects. These ion–molecule reactions, however, are all believed to proceed at rates close to the Langevin rate and this leaves little scope for isotope effects.

Perhaps the dissociative recombination reactions in equations (4) and (6) exhibit isotope effects of the requisite magnitude,

although the theory of secondary isotope effects in unimolecular reactions<sup>1,5</sup> indicates that the deuterium-containing species would decompose more slowly at the low pressure limit. It seems important to clarify this, either experimentally or theoretically. It would help if the  $\text{NH}_2\text{D}/\text{NH}_3$  ratio could be established by observations. Resolution of the problem is urgent because otherwise we must conclude either that the ion-molecule scheme of galactochemistry is inadequate or that the dense molecular clouds are enriched overall in deuterium by a handsome margin compared with the 'standard' cosmic abundance of  $\text{D}/\text{H} = 2 \times 10^{-5}$ .

## Lost Pacifica continent

THE Alpine mountain chain is generally accepted to be the product of continent-continent collisions. In this belt the zone of recent tectonic activity is wide (up to 2,000 km in Tibet) and crustal thickness in places is 1.5–2 times the average continental crust, presumably due to the inability of light continental material to sink into the asthenosphere. Under the Himalayas, for example, the crust is 70 km thick<sup>1</sup>. Furthermore, as indicated by seismicity, the active collision zone here includes not only the highly deformed Himalaya belt but also the entire Tibet plateau. Major wide mountain belts exist, morphologically similar to the Alpine belt, in regions which do not experience continental collision, such as western North America, Alaska, east Siberia and the Andes. The crustal thickness here can also be very great, up to 70 km in the Andes<sup>2</sup>. All are seismically active, wide, highly deformed and include high plateaus of various sizes. Many of these wide orogenic belts also exhibit great geological complexities which are not simply explained by the model of an oceanic lithosphere under-thrusting a continental lithosphere. We suggest, therefore, that the circum Pacific mountain belts may be the result of past continental collisions, similar to those associated with the Alpine belt. We summarise the evidence for the incorporation of past continental masses around the Pacific Ocean. Holmes<sup>3</sup> has given a compelling case for large continental land masses during parts of late Palaeozoic to early Tertiary to the west of North America such as Cascadia and Llanoria<sup>4</sup>. The land includes conglomerates derived from crystalline sialic rocks which have since disappeared. Hamilton<sup>5</sup> and Davis and Armstrong<sup>6</sup> suggested that the Klamaths were originally some distance offshore to the west and that the Permo Triassic Sonoma Orogeny results from an arc continent collision.

A large scale collision of Alaska with a continental fragment during Palaeozoic and early Mesozoic, finally coalescing in late Jurassic–early Cretaceous times has been suggested<sup>7–9</sup>. Hamilton<sup>5</sup> has proposed that Permian terrains

bearing Tethyan fusulinids may have formed in the central Pacific on island arcs which were subsequently swept into the North American continent. Furthermore, these North American terrains share Jurassic and Cretaceous faunas and floras with New Zealand, Caledonia, the Antarctica peninsula and Chile. This is consistent with several palaeomagnetic studies<sup>10,11</sup> which suggest that large fragments in the western USA, Canada, and in Alaska were located near the equator perhaps at Triassic times. Hillhouse<sup>12</sup> found that tholeiitic flows in the Wrangell mountain area were formed at 15° north or south of the equator during Triassic time.

Jones *et al.*<sup>13</sup> have shown that a large continental block—Wrangellia—was incorporated in north-western North America in late Mesozoic time. This block(s)<sup>14</sup> extending over 2,000 km from Alaska to Oregon, were not contiguous to central Alaska at Jurassic time.

Most remarkably, the displaced Wrangellia block apparently received enormous quantities of Triassic tholeiitic basalts—to become one of the largest domains of non oceanic basalts<sup>13</sup>. Jones proposed that presumably, rifting initiated this volcanism, but where it occurred and what was rifted remain enigmatic.

In Central and South America there are numerous old basement inclusions within the mobile belts, some of which extend well into the Pacific Ocean itself—suggesting past continental collisions. During the Jurassic, South America was bound to the west by volcanic rocks resting on strongly folded and metamorphosed rocks off Patagonia<sup>15</sup>, Ecuador<sup>16</sup>, Peru<sup>17,18</sup> and Bolivia<sup>19</sup>. Old Precambrian continental basement fragments, of unknown origins, were recognised also in the Santa Marta mountains in Columbia, the Serrania de Baudo in Panama and Columbia, the Pacific Ocean off Peru, the Nicoya complex in Central America, and the Sierra Madre de Sur in Mexico<sup>18</sup>, among others. Palaeomagnetic data<sup>20</sup> suggest that Honduras was in the Pacific in Cretaceous times.

The situation is perhaps best summarised by James<sup>21</sup>: Jurassic volcanic rocks in southern Peru are wedged in among crystalline metamorphic rocks at least 400 Myr-old. What these remnants of ancient sialic crust are doing some 300 km west of the currently exposed geosynclinal rocks of the continental margin is unknown. These rocks could be part of the palaeozoic microcontinent that lay to the west of the South American coastline.

In north-east Asia palaeomagnetic data<sup>22</sup> suggest that the Kolyma block and the Sikhote Alin region have been welded onto the Asian continent, probably in late Jurassic or Cretaceous times. The Verkhoyansk and Sikhote mountain belts represent, therefore, probable sites of continental collisions<sup>23</sup>. Other possible continental fragments from the Pacific Ocean are the Sea of Ohotzk and surrounding areas in early Tertiary time, almost all of China south of 40°, and Korea<sup>24,25</sup>. All this may suggest that large fragments have collided with mainland Asia during Triassic through Cretaceous time. Furthermore, Churkin and Eberlein<sup>14</sup> point out that Permian rocks lie outboard of poorly known Palaeozoic and Precambrian rocks in the Alaska range. Ancient rocks reappear west of the Bering Sea along the north-west rim of the Pacific, where similar terrains of Palaeozoic age occur in north-eastern USSR, in Japan, and discontinuously further south along the west Pacific rim. Thus not unlike North America and the Andes, mysterious continental masses in the Pacific have been involved in East Siberia, China and Japan. Many of these bodies bear strong evidence for continental origins as indicated by the nature of the old rocks exposed.

We propose that these chunks were parts of a continental mass which has disaggregated, perhaps the way Gondawana has, and Africa is and may continue to disaggregate. We envisage that the circum Pacific fragments were embedded in the major plates of the Pacific Ocean—the Kula,

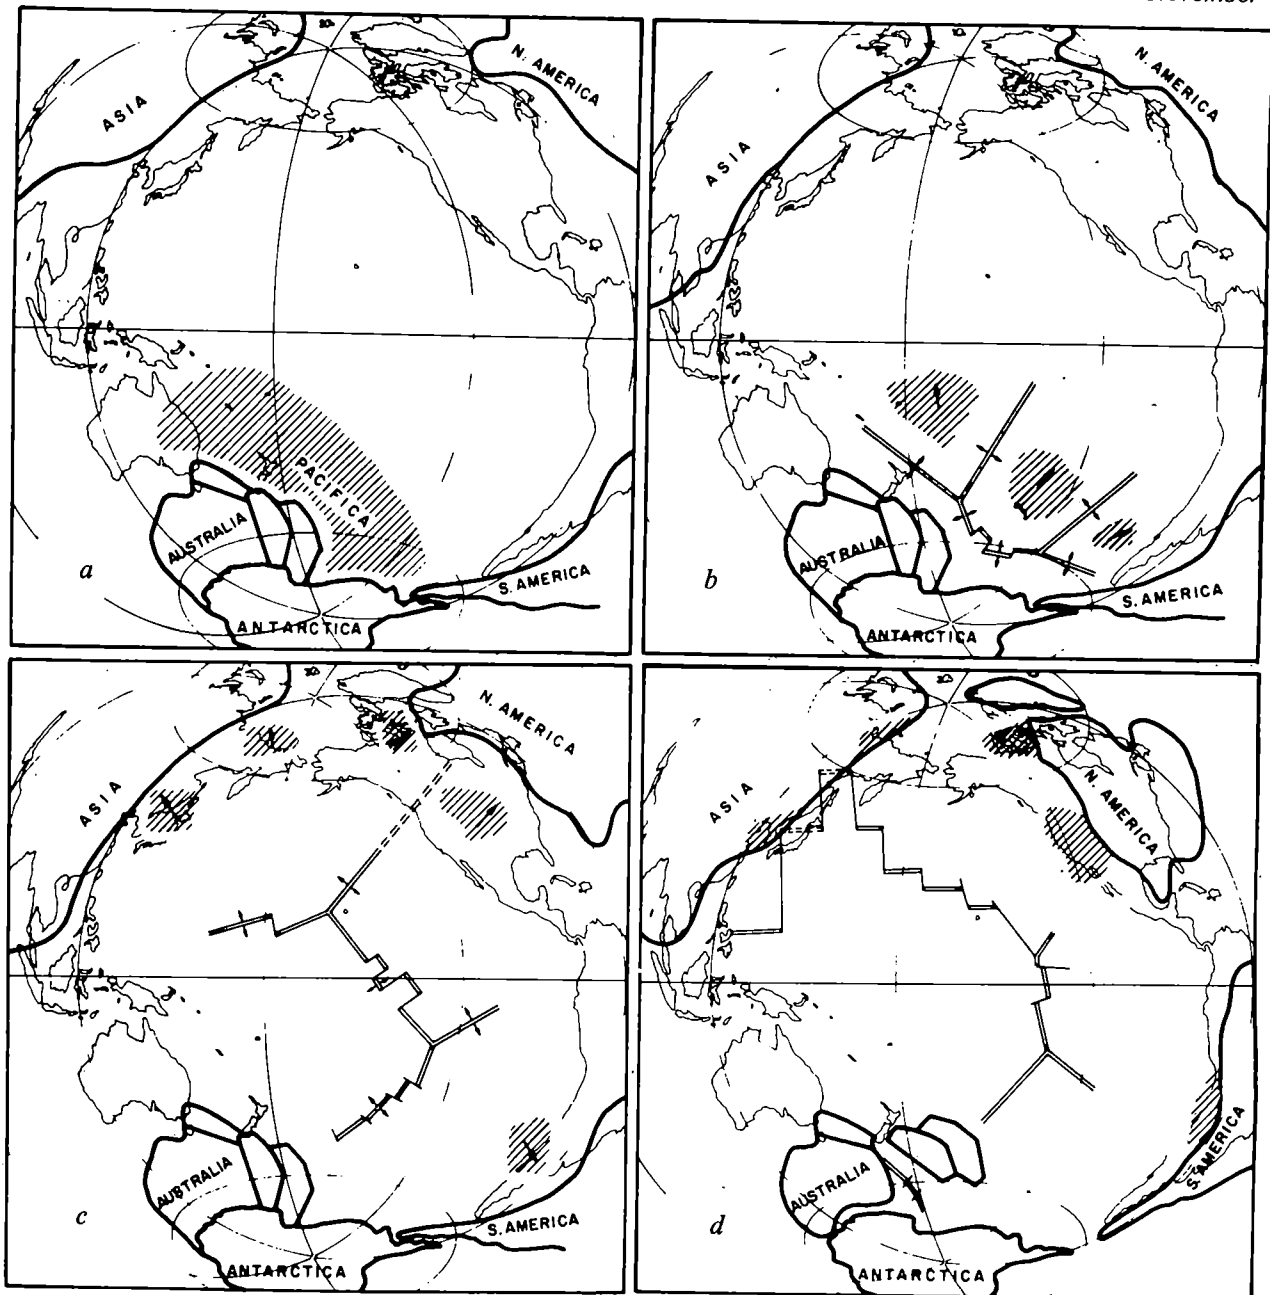

Fig. 1 Schematic model of the breakup of Pacifica and the resulting collision events. Possible ages of the reconstruction stages: *a*, 225 Myr; *b*, 180 Myr; *c*, 135 Myr; *d*, 65 Myr. Fine lines mark the present day continental outline. Heavy lines mark the location of the various continental areas through the geological evolution after Dietz and Holden<sup>39</sup>. Position of spreading centres simplified from refs 25, 26, 40–42.

Farallon, Phoenix and Pacific plates—whose motion might roughly be reconstructed from palaeomagnetic data back to 190 Myr BP<sup>25,26</sup>. As shown schematically in Fig. 1 we do this by removing continental blocks from Alaska and western North America, the Andes, Kamchatka and Japan, displacing them in a cartoon like fashion back in time attached to their corresponding plates. The various fragments, as they migrate back towards their respective spreading ridges, also approach each other. By further extrapolating the plate motions backwards beyond Jurassic time, we suggest that they comprise a single mass perhaps by mid-Permian times.

We call this mass Pacifica<sup>32</sup>—to emphasise its centrality in the Pacific geological history. Assuming that Pacifica was located over the developing spreading pattern of Larson and Chase<sup>25</sup> we imagine four major groups of continental fragments—one each on the Kula, Farallon, Phoenix and Pacific plates. As spreading continued, these fragments

were presumably carried along toward subduction zones, eventually reaching continental margins. Roughly speaking the Kula fragments collided with Alaska and Eastern Siberia, the Farallon fragments with North America and the Phoenix fragments with South America. The submerged platforms in the south-west Pacific (which show typical crustal structures) such as the Ontong-Java and Manihiki platforms may thus be fragments of Pacifica.

Before its breakup Pacifica could have been somewhere in the neighbourhood of Australia, as shown in Fig. 1. We chose to extend Pacifica to Proto Antarctica, to account for the possibility that southern South America may be a splinter off Antarctica<sup>27</sup> and that at least parts of the Antarctica coast does consist of rifted margins<sup>28</sup> indicating continental rifting.

The existence of Pacifica may thus explain the origin of the circum Pacific Cordillera, and probably shed some light on the origin of the submerged platforms in the

south-west Pacific Ocean<sup>29,30</sup>. It may provide the continental connection between western North America, south-east Asia, Australia, and South America, needed to explain the evolutionary history of flora, such as the angiosperms<sup>31,32</sup>, and fauna, such as various fusulinids<sup>3</sup> and mammals<sup>33,34</sup> around the Pacific. In fact, the concept of a Pacifica was first introduced by biogeographers<sup>32,35-37</sup> solely to explain the relation between the species and families surrounding the Pacific. Our results may, therefore, provide the geophysical and geological detail necessary to understand the continental and biological history in the Pacific. We believe that the combined evidence from geophysics, geology and biology makes a compelling case for a now extinct Pacifica continent, whose fragmented remains are mostly now embedded in the circum Pacific mountain belts.

## Rb-Sr ages of early Archaean supracrustal rocks and Amitsoq gneisses at Isua

PREVIOUS field descriptions<sup>1-4</sup> and isotopic age determinations<sup>5,6</sup> left unresolved several important points about the relationships between the Isua supracrustal rocks and the surrounding Amitsoq gneisses. In scattered areas of comparatively low deformation, field relationships show unequivocally that

gneissose granitic veins intrude the supracrustal sequence. Geochemical studies<sup>7</sup> show that these veins are closely comparable to early tonalitic components in the polyphase Amitsoq gneisses surrounding the supracrustal belt. Here we show that the veins are isotopically indistinguishable from the main outcrops of Amitsoq gneisses. They do not represent a period of granitic activity significantly younger than the Amitsoq gneisses, such as the ~2,900 Myr-old Nûk gneisses of the Godthaab area. Thus the veins may be classified as Amitsoq gneisses. Present field and isotopic evidence combined suggest that at least part of the ~3,700 Myr-old Amitsoq gneisses are younger than the Isua supracrustal belt. We have found no field or isotopic evidence that any part of the Amitsoq gneisses so far mapped pre-date the deposition of the supracrustals.

It was also uncertain whether quartzofeldspathic gneisses so far studied isotopically from the Isua area (West Greenland) were representative of the main body of Amitsoq gneiss in that area. The earlier material studied was collected largely from gneisses close to the supracrustal rocks. Most of the samples are strongly foliated rocks in which primary igneous features had been lost during deformation. In contrast Amitsoq gneisses with original structures away from the immediate contact of the supracrustal succession were represented by only a few samples. It was thought possible that the rocks in the contact zone could represent a separate unit, either a screen of granite material emplaced along a tectonically controlled zone between an old gneiss basement and a younger cover or a group of greywacke-like sediments deposited on gneissic basement.

The material already studied isotopically<sup>5,6</sup> was supplemented by samples collected by Bridgwater and McGregor in 1973 of which the field relations were better known. Three groups of rocks were selected for further Rb-Sr age study: (1) veins of tonalitic gneiss up to several metres in width which cut across an earlier foliation in Isua amphibolitic supracrustal rocks outcropping to the west of the lake Imarssuaq (Fig. 1). These have tonalitic or granodioritic compositions comparable to the majority of Amitsoq gneisses (samples 158528-530). (2) Massive, granodioritic Amitsoq gneiss collected approximately 2.5 km north of the contact between supracrustals and gneisses east of Imarssuaq (samples 117991-993). (3) Homogeneous, muscovite-bearing, leucocratic schist found as a major unit over 100 m wide within the supracrustal succession to the west of Imarssuaq (samples 158509, 158526, 158526A). These were considered by Bridgwater and McGregor to be either acid volcanics or more highly deformed equivalents of the discordant tonalitic veins described in (1) above. Thin section and chemical studies<sup>7</sup>, however, have shown that they are closely related to K-rich boulders found within the conglomeratic unit which forms a conspicuous part of the southern and eastern parts of the Isua succession<sup>1-4</sup>. Further mapping by Allaart<sup>3,4</sup> has shown that this unit of leucocratic schist adjoins the westward continuation

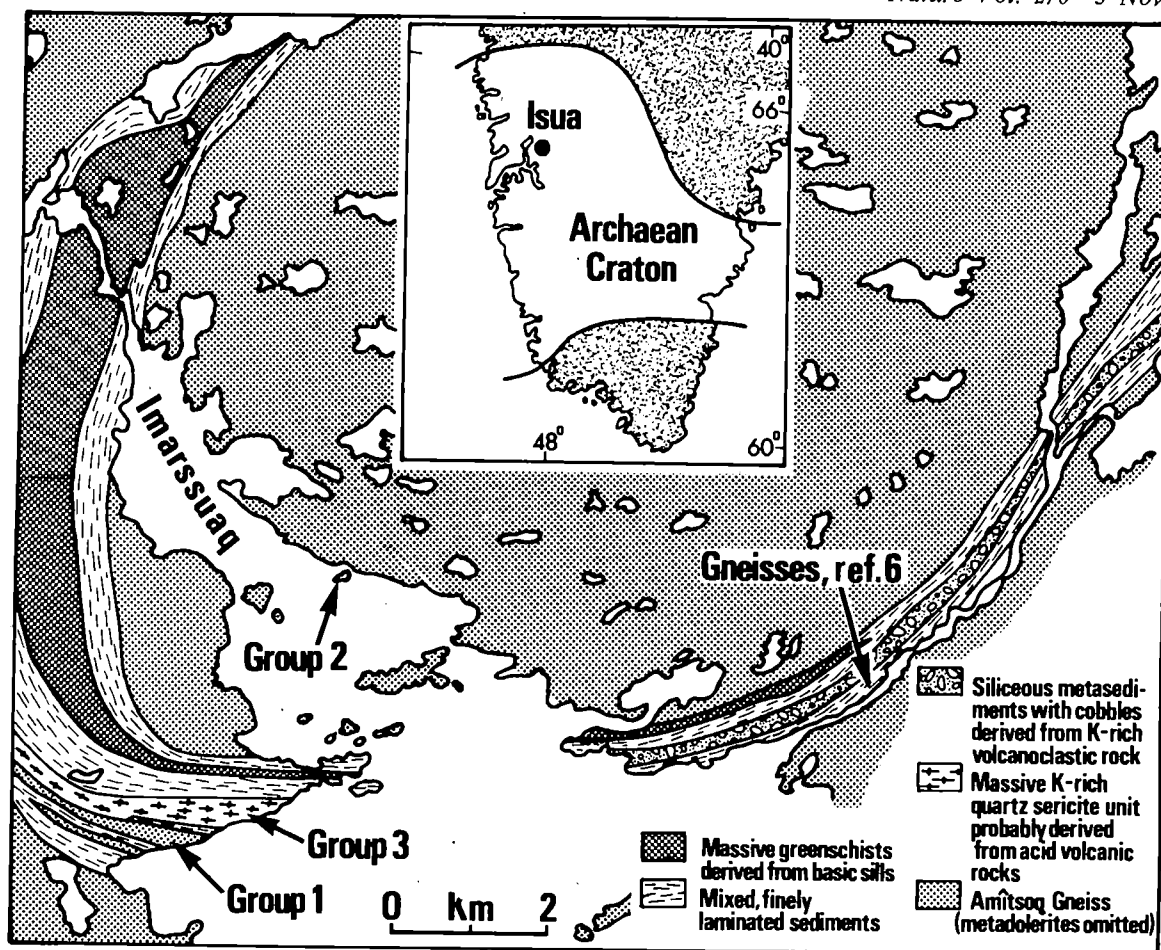

Fig. 1 Simplified geological sketch map of Isua area, after Allaart<sup>3,4</sup> with specimen localities shown.

of the conglomerate beds. The muscovite schists are now regarded as belonging to the same suite of acid, volcanogenic rocks as the conglomerate. They may be derived from acid lavas that were the source rocks for many of the boulders found in the adjacent volcanogenic conglomerate.

Table 1 shows Rb-Sr whole rock analytical data on three samples from each of the three groups listed above. Full details of chemical and mass-spectrometric techniques have been described elsewhere<sup>8</sup>. Rb/Sr ratios were determined by a precise X-ray fluorescence technique<sup>9</sup>. The decay constant of <sup>87</sup>Rb was taken as  $1.39 \times 10^{-11} \text{ yr}^{-1}$ .

Fig. 2 Rb-Sr whole rock isochron plot for Amitsoq gneisses from Isua. ○, Gneissic veins cutting supracrustals (Group 1, Table 1) and Gneisses far away from contact with supracrustals (Group 2, Table 1). +, Gneisses from near contact with supracrustals (for full details and analytical data, see ref. 6).

The groups are rather small to be treated individually but may be regressed in combination with each other and with published data. Groups 1 and 2, respectively representing gneissic veins cutting supracrustal rocks and Amitsoq gneiss well away from the contact, give a combined isochron age of  $3,750 \pm 200 \text{ Myr}$  (all errors on ages quoted at  $2\sigma$ ), and initial  $^{87}\text{Sr}/^{86}\text{Sr}$  of  $0.7008 \pm 14$  (also quoted at  $2\sigma$ ). The isochron fit is not perfect and analytical errors would have to be magnified by a factor of 3 to achieve perfect fit. When these data are regressed together with a published 7-point whole-rock isochron<sup>6</sup> of  $3,780 \pm 130 \text{ Myr}$  and initial  $^{87}\text{Sr}/^{86}\text{Sr}$  ratio of  $0.6998 \pm 12$  for Amitsoq gneiss from close to the margin with the supracrustal rocks, the combined data yield an isochron giving an age of  $3,720 \pm 60 \text{ Myr}$  and initial  $^{87}\text{Sr}/^{86}\text{Sr}$  ratio of  $0.7008 \pm 6$  (Fig. 2). This demonstrates that the gneissic veins of Group 1 and the Amitsoq gneisses were formed within a period covered by the analytical error on each rock suite. We, therefore, consider them to be contemporaneous and that the Isua supracrustals pre-date the Amitsoq gneiss.

The three samples of Group 3 yield an isochron with an age of  $3,760 \pm 70 \text{ Myr}$  and initial  $^{87}\text{Sr}/^{86}\text{Sr}$  of  $0.7014 \pm 15$ . When regressed together with five out of six published analyses<sup>6</sup> on the probably closely related (see above) boulders and matrix from the Isua conglomeratic unit<sup>3,4,7</sup>, the combined isochron gives an age of  $3,740 \pm 60 \text{ Myr}$  and initial  $^{87}\text{Sr}/^{86}\text{Sr}$  of  $0.7015 \pm 17$  (Fig. 3). (The omitted sample from ref. 6 is 158538.) The six published analyses gave an errorchron of  $3,860 \pm 240 \text{ Myr}$ , with an intercept of  $0.675 \pm 40$ . The far more precise results reported here are due to the much greater range of Rb/Sr ratios for the combined data, as well as the omission of one of the published values. The revised age agrees well with a Pb-Pb isochron age of  $3,760 \pm 70 \text{ Myr}$  for the banded iron formation member of the Isua supracrustal sequence<sup>5</sup>.

The following principal conclusions may be drawn from these data. First, gneissic veins which intrude the Isua supracrustal sequence yield Rb–Sr whole rock ages indistinguishable from the surrounding Amitsoq gneisses. Together with fragments of greenstone belt-type lithologies (Akilia association) enclosed in Amitsoq gneisses elsewhere in the Godthaab district<sup>10</sup> the Isua supracrustals are the oldest rocks recognised in the Archaean of West Greenland.

Second, the Isua supracrustals and surrounding Amitsoq gneisses are all between ~3,700 and 3,800-Myr-old, although the actual age difference between the two rock units is probably too small to resolve by Rb–Sr and Pb–Pb whole-rock age methods. U–Pb methods on zircons may offer more hope in this respect<sup>11,12</sup>. Thus, a U–Pb zircon date of  $3,600 \pm 50$  Myr has been reported on Amitsoq gneisses from the Godthaab area<sup>11</sup>, whilst a U–Pb zircon date of  $3,824 (+12 \text{ or } -9)$  Myr has been reported from metavolcanic boulders in a large conglomeratic unit within the Isua supracrustals<sup>12</sup>. Unfortunately, no zircon U–Pb dates have yet been published for the Amitsoq gneisses at Isua.

Fig. 3 Rb–Sr whole rock isochron plot for Isua supracrustal rocks. ○, Schists (Group 3, Table 1). ×, boulders and matrix from conglomeratic unit (for full details and analytical data, see ref. 6).

Finally, initial  $^{87}\text{Sr}/^{86}\text{Sr}$  ratios are in the range ~0.700–0.702 and suggest, in agreement with previous views<sup>13,14</sup>, that the precursors of these early Archaean rock units had not existed with average crustal Rb/Sr ratio for more than about 100 Myr before the measured age.

We thank R. Goodwin and M. Humm for technical assistance; the Natural Environment Research Council and the Geological Survey of Greenland for support.

## Laser speckle photography in a fluid medium

A TECHNIQUE for obtaining quantitative velocity data from hydrodynamic flow fields using laser speckle photography (LSP) has been developed and uses the scattered light from the interior of a suitably seeded liquid which is illuminated by a coherent beam from a pulsed ruby laser. The resulting speckle pattern can be photographed on high resolution film. A doubly exposed photograph of the correlated speckle patterns produced by fluid dynamic motion contains all the information necessary to describe the motion throughout a selected plane. When the speckle photographs are optically interrogated distinct fringe patterns are produced whose geometries are related to the velocity field. Here we describe how a Poiseuille flow was used to demonstrate this novel technique. Doubly exposed speckle photographs and typical fringe patterns illustrating the velocity distribution are given, analysed and compared with the classical theory.

The LSP technique has been used since 1969 almost exclusively for various applications to surface metrology<sup>1–3</sup>. Barker and Fournay<sup>4</sup> have extended the method to measure displacements in the interior of a transparent solid by recording side-scattered light from an illuminated domain. With lasers of conventional power such recordings require very long exposures. Consequently, the few applications reported so far have examined only imposed static strains. The basic difference between that work and the present application to fluids is that the latter is truly dynamic involving moving liquids rather than static solids.

The extension of side-scattering speckle techniques to fluid dynamic situations has been achieved by using a double pulsed Q-switched ruby laser and a suitably seeded medium. The experimental arrangement used to record speckle photographs of the flow field is shown in Fig. 1. The beam from a ruby laser, which

Fig. 1 Experimental arrangement for side-scattering LSP.

Fig. 2 Typical laser speckle photograph and diffraction fringe patterns from radial locations as shown; *a*,  $r/R = 0$ ; *b*,  $r/R = 0.32$ ; *c*,  $r/R = 0.53$ ; *d*,  $r/R = 0.74$ .

delivers 2–4 J in each 20-ns pulse, is condensed by lens  $L_1$ . A negative lens  $L_2$  is placed ahead of the focal point of  $L_1$ . From the virtual focus of  $L_2$  the beam is expanded and collimated into a vertical planar sheet about 40 mm high and 1–1.5 mm thick by the cylindrical lenses  $C_1$  and  $C_2$ . A slit may be inserted at the observation cell to assure a beam of uniform 1 mm thickness, but is not essential. The above arrangement of optical components specifies the interior plane of study and optimises the amount of light available to be side-scattered from the flow field.

To demonstrate the technique, a Poiseuille flow was established in a quartz tube using glycerine seeded with a minute quantity of

white latex paint ( $\sim 0.01$  ml per l). Refraction effects due to the curvature of the tube were minimised by enclosing the illuminated portion in a liquid gate filled with an index matching fluid. The correlated speckle patterns were recorded on Agfa-Gevaert 10E75 high resolution film. Double-exposed speckle photographs, with time separations of 10–15 ms were recorded at a magnification  $m$  of 2.1 and lens apertures between  $f/2.8$  and  $f/4$ . At the ruby wavelength  $\lambda = 694.3$  nm, the Rayleigh resolution criterion

$$s_0 = \frac{1.2 \lambda f (1+m)}{m} \quad (1)$$

estimates the speckle size in the object plane to be  $3.4 \mu\text{m}$  and  $4.9 \mu\text{m}$  for the apertures quoted above. These speckles form a very fine random grid which moves with the medium in the illuminated plane. Therefore, a double-exposed photograph of the side-scattered light contains two correlated grids which can be analysed as a non-uniform diffraction grating. This technique can be used successfully only where the displacement between exposures is greater than the speckle diameter, but not so great as to destroy correlation. In this study, which included more than the two examples discussed here, the displacements that were most readily resolved ranged between 2 and 20 speckle diameters.

Figure 2 shows a typical double-exposed speckle photograph, and several diffraction fringe patterns which were obtained by interrogating it at various radii across a diameter of the tube. The interrogation was accomplished by illuminating the speckle photograph with a narrow beam of coherent light which diffracts into a pattern of Young's fringes. The spacing and orientation of the fringes are related to the displacement field at the point of interrogation. Specifically, the displacement of the medium,  $d$ , is related to the angular spacing of the fringes,  $\alpha$ , and the magnification,  $m$ , by

$$\sin \alpha = \lambda/dm \quad (2)$$

where  $\lambda$  is the wavelength of the interrogating beam. In addition, the displacement vector in the illuminated plane is always normal to the direction of the diffraction fringes at each point. Because Poiseuille flow is steady and unidirectional, the fringes are

Fig. 3 Comparison between the LSP data and the classical Poiseuille theory.  $\circ$ ,  $Q = 0.53 \text{ ml s}^{-1}$ ,  $\Delta t = 10 \text{ ms}$ ;  $\bullet$ ,  $Q = 0.264 \text{ ml s}^{-1}$ ,  $\Delta t = 10 \text{ ms}$ .

everywhere perpendicular to the tube axis and the spacing varies continuously and identically across any diameter. In general, in flow-fields which are not unidirectional the fringe patterns will be less regular.

Analysis of a series of diffraction patterns across a diameter gives the fluid displacement as a function of radius,  $r$ . Thus the velocity distribution can be obtained directly since the pulse separation is known. Figure 3 gives the velocity,  $v$ , for two time separations and flow rates,  $Q$ , compared with the classical distribution

$$v(r) = \frac{2Q}{\pi R^2} \left( 1 - \frac{r^2}{R^2} \right) \quad (3)$$

where  $R$  is the radius at the wall. The agreement between the LSP data and the classical theory is very good over most of the tube diameter. Near the walls, however, positional errors due to refraction are apparent because of the 0.7% refractive index mismatch between the fused silica and the glycerine.

The side-scattered LSP technique therefore offers an attractive alternative to the existing methods of studying fluid dynamic flow fields. In contrast with conventional interferometric techniques, side-scattered LSP measures the velocity field explicitly, and can examine a uniquely defined interior plane rather than integrating the results through the entire volume thickness.

## Mean residence times in continuous flow systems

INDIVIDUAL elements of a material which enters a system at a constant rate, resides for some time, and then leaves, can take different paths through the system, travel at different speeds, and be delayed for many reasons. For example, by diffusing into stagnant zones, or by transferring, perhaps across a membrane, into a separate phase, they may take part in any activity that does not destroy them which does not preclude chemical reaction where atoms of flow material (which may be combined in any way with other components in the flow streams) are being considered. The process must, however, be a steady-state one, which implies that the quantities of material or 'holdups' in all parts of the system do not vary with time, and that the rate at which material leaves the system is equal to its rate of entry. As an example, we could consider a stretch of river swept by water, or an effluent component in the water; or a continuous chemical reactor into and out of which a conserved material (atoms or ions perhaps) flows at a constant rate; or a respiratory system, fed with oxygen which is transported to the various parts of the body before leaving in part as carbon dioxide. At first sight it seems unlikely that quantitative deductions of the behaviour of so abstract a structure are possible; however, one such deduction has been made<sup>1</sup>, and this letter reports another.

The residence time distribution,  $f(t)$ , of the material component considered, completely defines the general system: thus, the fraction of key material leaving the system, that has resided in the system for a period of time in the interval  $(t, t+dt)$ , is  $f(t)dt$ . Buffham<sup>1</sup> has generalised a well established result for simple flow systems, showing that the mean residence

Fig. 1 Block diagram for the general system: the steady flow rate of the key material component is  $Q$  and its residence time distribution is  $f(t)$ ; its total holdup in the system is  $H$ .

time of material,  $\mu$ , is independent of the internal characteristics and always equal to the ratio of total holdup of the material to its overall flow rate through the system. Figure 1 and equation (1) summarise this.

$$\mu = \int_0^\infty t f(t) dt = H/Q \quad (1)$$

Obvious uses of this are in the measurement of the holdup of the component, or its overall flow rate, where the residence time distribution can be determined by tracer techniques<sup>2</sup>, but its usefulness goes well beyond these direct applications. For example, it has been central to the development of a model-independent theory of chromatography<sup>1</sup> which supercedes previous treatments, based on specific models of the chromatographic process, by obviating the restrictive assumptions on which those are founded.

We shall now use the basic relationship shown in equation (1) to make deductions about arbitrarily defined internal regions of the general system; a more complete proof of the final result, equation (2), will be published elsewhere.

Consider the general system divided into  $n$  regions having holdups of the key flow material  $h_1, h_2, \dots, h_n$  where

$$\sum_i h_i = H$$

The residence time distributions of the material in those regions is denoted by  $f_1(t), f_2(t), \dots, f_n(t)$  respectively. In general, an element may enter a region any number of times; however, periods of residence that make up these distributions refer to total times spent by elements in the respective regions before they leave the system. The period of residence of a material element in the system will be the sum of its residence times in the  $n$  regions. Assuming these separate periods of residence to be independent of each other (and it is difficult to think of a steady-state system where this condition is not satisfied), then the distribution of the sum of residence times in the various regions,  $f(t)$ , may be obtained by convolution<sup>3</sup>. Thus the  $n$ -fold convolution

$$f(t) = \int_0^t \int_0^{\lambda_1} \dots \int_0^{\lambda_{n-2}} f_n(t - \lambda_1) f_{n-1}(\lambda_1 - \lambda_2) \dots f_2(\lambda_{n-2} - \lambda_{n-1}) f_1(\lambda_{n-1}) d\lambda_{n-1} d\lambda_{n-2} \dots d\lambda_1$$

gives the total residence time distribution. This relationship is represented by Fig. 2 which is thus equivalent to Fig. 1.

Fig. 2 Block diagram of the general system that is equivalent, for residence time distribution purposes, to Fig. 1.

Fig. 3 Examples of simple continuous flow systems for which the general relationship of equation (2) may be readily verified for the shaded regions. Squares and rectangles represent perfectly mixed and plug-flow regions respectively.

Equation (1) may now be applied to any of the blocks of Fig. 2 with the result

$$\mu_i = \int_0^{\infty} t f_i(t) dt = h_i/Q \quad (2)$$

$i = 1, 2, \dots, n$

which states that the mean residence time of material in any region of the system is equal to its holdup in that region divided by its overall flow rate through the system as a whole.

This simple result is rather surprising. Figure 3 shows some trivial examples for which it may be readily verified for the shaded regions: although in each case, the residence time distribution of flow material in this region depends on the internal flow rate,  $q$ , the mean residence time does not and is given by equation (2).

These examples cease to be trivial if arbitrary mixing patterns are allowed in the regions as well as additional connections between them. Hence, Fig. 3a and b may well model the stretch of river referred to earlier with the shaded areas representing a relatively stagnant backwater; regardless of the descriptive complexities of such a system, equation (2) will hold for both regions and could be applied, say, to making a first estimate of the consequences of an upstream effluent discharge on the ecology of the backwater. Another application could be in predicting the exposure of various regions of a system to a radioactive tracer introduced, for diagnostic purposes, into a flow stream to which they may be only indirectly connected: numerous systems, including physiological ones, are frequently tested in this way.

## *Centroceras*, the 'missile'-launching marine red alga

VEGETATIVE reproduction by specialised structures is very rare in the red algae. Dixon<sup>1</sup> has listed two cases among freshwater species and two unconfirmed reports from the nineteenth century among marine species. I report here that the marine red alga *Centroceras* produces missile-shaped propagules which are carried away by ocean currents.

Although recorded only six times since its discovery in the Red Sea in 1849<sup>2–5</sup>, *Centroceras* seems to be quite common in the epiphytic community of the leaf surfaces of seagrasses, and to a lesser extent, larger attached algae. It is, however, inconspicuous due to intensive grazing by the many herbivorous fish of the region.

'Clean-looking' *Halophila stipulacea* (Forssk.) Aschers, plants were cultured in the laboratory. Undisturbed by fish, the epiphytic algal rudiments attached to the leaves developed within 4 d to give a luxuriant growth clearly visible to the naked eye. Among the algae isolated from this growth was *Centroceras*. (The Red Sea populations have usually been referred to as *C. clavulatum* (C. Ag.) Mont.<sup>3,6–8</sup> or *Ceramium clavulatum*<sup>4,5</sup>.) Our *Centroceras* plants differed from other *C. clavulatum* populations in showing: (1) two branching patterns at the apex regions (Fig. 1); (2) limited growth of lateral branches while attached to the parent plants; (3) unpigmented cortical cells of the lowermost internode of the lateral branches; (4) rhizoids just above the first node of the lateral branch, and (5) missile-shaped lateral branches that dropped off and were carried away as propagules.

When they reached the bottom of the culture dish, the propagules resumed growth, attached themselves to the

Fig. 1 Monopodial unilateral branching of 'missile'-bearing branch of *Centroceras* from the Red Sea. Scale bar, 250  $\mu$ m.

substrate by rapid elongation of their rhizoids and elongated rapidly. Within a few days, sometimes as soon as 4 d, the developing plants were large enough (7–10 mm long) to produce 'missiles' of their own. A great many such 'missiles' were produced by one parent plant.

Attempts to find 'missile'-bearing plants of *Centroceras* in *Halophila* beds failed as no *Centroceras* growth could be detected on the leaves. But it was found on leaves of another seagrass, *Thalassodendron ciliatum* (Forssk.) den Hartog. Unlike *Halophila*, *T. ciliatum* has leaves which are largely horizontally orientated, often forming a close canopy which prevents fish from reaching the lower leaves and facilitates undisturbed development of epiphytic algal growth.

In the sea the numerous tiny 'missiles' produced by *Centroceras* plants which escape the teeth of fish, would be carried away easily by currents and spread over large areas, to settle on leaves of seagrasses and other suitable surfaces. They serve both as long-range dispersal units and as a means to ensure quick development of the future plant which in a very short time produces new dispersal units, before falling prey to grazing fish. There are many species of herbivorous fish in tropical seas, and it may be assumed that the production of the missile-shaped propagules by *Centroceras* in the Red Sea and probably in other areas of the Indopacific region, evolved as a result of heavy grazing pressure.

In that case, other delicate algae of similar habitats there and in other tropical regions can be expected to have reacted to grazing pressure by producing specialised vegetative reproductive structures yet to be discovered.

## Phytochrome-regulated organogenesis in lettuce tissue culture

LIGHT intensity and daily photoperiod are known to affect organ development in tissue culture<sup>1</sup>, but little information is available on the spectral region influencing organogenesis. Studies with tobacco callus have shown that shoot initiation is enhanced by blue light<sup>2,3</sup> and that red light has no influence. Red light, on the other hand, promotes callus growth and adventitious bud formation in some species<sup>4,5</sup> and induces the elongation of endogenous buds in cultured root segments of *Convolvulus arvensis* L.<sup>6</sup>. The latter phenomenon is regulated by phytochrome<sup>6</sup>. In the culture conditions described here, lettuce cotyledon cultures develop well-formed shoots under daily (16-h photoperiod) irradiation from broad-band emitting fluorescent lamps. Dark-grown control cultures, on the other hand, form significantly fewer shoots. We describe here the enhancement of shoot formation in lettuce cotyledon cultures by red light and demonstrate that organogenesis is under phytochrome control<sup>7</sup>.

Explants (3 × 2 mm) from the distal regions of the cotyledons were obtained from dark-grown, 5-d-old germinated seeds of *Lactuca sativa* var. 'Black Seeded Simpson'. Excision and planting were done under low intensity (~4.5 μW cm<sup>-2</sup>) 504-nm light to which the cultures are not sensitive. The explants were grown on MS salts<sup>8</sup> supplemented with indole-3-acetic acid 1 mg l<sup>-1</sup>, kinetin 0.5 mg l<sup>-1</sup>,

adenine sulphate 40 mg l<sup>-1</sup>, thiamine-HCl 0.1 mg l<sup>-1</sup>, nicotinic acid 0.5 mg l<sup>-1</sup>, pyridoxine-HCl 0.1 mg l<sup>-1</sup>, glycine 2 mg l<sup>-1</sup>, myo-inositol 100 mg l<sup>-1</sup> and sucrose 30 g l<sup>-1</sup> (ref. 9). Before addition of Bacto-Agar (Difco) 10 g l<sup>-1</sup>, the medium was adjusted to pH 5.8. The 660-nm red light source was described previously<sup>3</sup>. The far-red source was a narrow-band emitting fluorescent lamp with peak emission at 744 nm (Phosphor E-5346, GTE) from which light below 700 nm was absorbed by FRF-700 plexiglass filter (Westlakes Plastics).

Table 1 shows the results of 5-min daily exposures of lettuce cotyledon cultures to 660 nm, 740 nm, or 660 nm followed immediately by 740 nm light. After 35 d, red light caused a 2- to 2.5-fold increase in the number of shoots and a 1.5-fold increase in callus weight compared with control cultures not exposed to light. Far-red light had no effect on the number of shoots produced but decreased the callus weight slightly. Red followed by far-red light reversed the red light effect on both shoot formation and callus growth. These results demonstrate that both increased shoot formation and callus growth are regulated by the low-energy phytochrome photoreceptor system.

The above data do not indicate at what stage of shoot development red light is effective. For example, light may simply cause elongation of shoots from pre-existing buds as is the case with *Convolvulus arvensis*<sup>6</sup>. To examine this point, both bud and shoot formation were observed at an earlier stage of development. Table 2 shows that red light

**Table 2** Red light-induced bud and shoot formation in lettuce cotyledon cultures after 14 d of exposure

Treatment	Sample size	No. of buds	No. of shoots
Expt 1			
Control	30	11.23 ± 0.74	1.47 ± 0.22
5 min R per d	26	20.34 ± 1.14	3.00 ± 0.34
Expt 2			
Control	7	10.00 ± 0.82	1.29 ± 0.52

Conditions were as in Table 1.

doubles the number of buds as well as shoots present in the cultures after only 14 d of exposure. Thus, light regulation of shoot production occurs at the bud stage of development and perhaps at the bud initiation stage.

To our knowledge this report is the first demonstration of phytochrome-regulated shoot morphogenesis in a tissue culture system. Lettuce cotyledon cultures, then, may serve as a useful, simple, model system for investigating the molecular mechanisms involved in phytochrome regulation of organogenesis.

## Graded localisation of naming from electrical stimulation mapping of left cerebral cortex

APPLYING a weak electric current to the cerebral cortex of awake neurosurgical patients is an established method for mapping language zones on the basis of stimulation-evoked errors. Two new findings are reported here—the topographical extent of language cortex in an individual subject can be wider than that proposed in the classic maps, and, within this zone different sites are variably committed to language as measured by the naming function.

Naming errors evoked by electrical stimulation of the brain in the presence of a retained ability to speak are useful indicators of the language function of focal areas of cortex. Weak electric currents at levels below that which produce after-discharges, deactivate a limited area of cortex abruptly and reversibly, not allowing the brain sufficient time to either compensate or reorganise. Furthermore, research on aphasia has established that lesions to any part of the language system will cause anomia, or naming errors.

In the most extensive studies of stimulation mapping of the cerebral cortex, Penfield and Roberts<sup>1</sup> reported aphasic-like errors from the classical left hemisphere language zones; these errors included distortion and repetition of syllables and words, confusion of numbers while counting, inability to name with retained ability to speak, misnaming and perseveration. What is not generally recognised, however, is that Penfield and Roberts only elicited a total of 132 aphasic errors in 110 patients; of these errors, 19 were misnamings and 51 were omissions with retained ability to speak, the two error categories most representative of anomia.

More recently, Fedio and Van Buren<sup>2</sup> recorded naming errors from left hemisphere stimulation in 19 patients; in their series, a total of 87 naming errors, primarily omissions, were observed, again clustering in the classic language zones. The small number of sites sampled in any one patient again precluded analysis of the extent and the variability of language representation in the lateral cortex of the individual.

In this report we address two related questions. First, the Penfield and Roberts composite map, derived from pooling the stimulation-error points across subjects, covers a large area of the left hemisphere; is any single individual's language cortex this extensive? Second, are specific areas of cortex within the zone equally involved in language function in a particular individual?

Data bearing on these questions were obtained from three adults with psychomotor seizures from left temporal or left temporo-parietal foci of early childhood onset. The persistence of the seizures despite anticonvulsant therapy indicated surgical treat-

ment. Pre-operative intracarotid sodium Amytal testing, which measured naming, reading and short-term verbal memory, identified the left hemisphere as the dominant one for language in all three patients.

The left fronto-temporo-parietal cortex was exposed at operation under local anaesthesia. Corticography was used to locate the epileptic focus; after that motor and sensory responses to stimulation mapped the Rolandic cortex, which is indicated by stippled circles on the left hemisphere tracing in Fig. 1. Language testing followed, using a set of achromatic slides, each one a line drawing of a different common object such as a bell, a hand, a car, a ring, with the words 'That is a', or 'This is a', printed above. The slides were projected at a constant rate, 4 or 5 s depending on each patient's ease of responding in the test-operative situation. The patient was required to say the words, for example 'This is a', and then to name the object. Testing was carried out in the patient's native language: English for number 1 and no. 3, Dutch for no. 2.

Stimulation was delivered through bipolar silver ball electrodes, 5 mm apart. The stimulations were bi-phasic square wave pulses, 2.5 ms total width at 60 Hz, delivered from a Nuclear Chicago constant current stimulator. The current levels were determined for each patient to be below the threshold for after-discharges in epileptic cortex and below the level of sensation in sensory-motor cortex. The current level for patient 1 was 7 mA in all sites, for patient 2, 8 mA in all sites. For patient 3 it was necessary to use a lower current in the epileptic cortex, 3 mA in the anterior temporal lobe and 4 mA in the posterior temporal lobe; 6 mA were used in the frontal and parietal lobes. Current was delivered in stimulation trains of the same duration as the naming slide presentations, initiated and terminated when the slide projector changed.

A grid pattern of sterile numbered tickets was laid out on the

**Fig. 1** Results from naming error tests depicted on left hemisphere angiogram tracings. Solid circles indicate points at which stimulation always produced a naming error in that patient. Shaded circles, points at which stimulation variably produced naming errors at least half of the time. A 50% error rate was chosen as the cut-off point because a lower error rate (given the small number of samples per site) could not unequivocally be distinguished from the non-stimulation control trial error rates. The control trial error rate for patient 1 was 12.8%, for patient 2 was 15.5% and for patient 3 was 14.1%. Sites which had stimulation error rates of less than 50% are indicated by an open circle containing an asterisk. Blank circles indicate sites at which stimulation never produced a naming error in that patient.

exposed cortex of each patient. For patient 1, 28 sites were selected, for patient 2, 23 sites were selected and for patient 3, 26 sites were selected. These sites are indicated in Fig. 1 by open and filled circles. The mean number of stimulation samples per site was 2.3 for patient 1, 2.2 for patient 2 and 3.1 for patient 3. No site was stimulated consecutively; stimulation was not applied during consecutive naming slides. Stimulation was applied to a site only if the immediately preceding object had been named correctly. Non-stimulation control trials were determined by the same criterion, the immediately preceding object had been correctly named.

We elected to score the errors conservatively, counting only omissions and substitutions, and disregarding both hesitations and slurring. If the correct name was spoken before the slide changed, it was counted as a correct trial; if the correct name was spoken after the slide changed, and therefore after stimulation had stopped, it was counted as an error. Substitutions, such as calling a 'fork' a 'spider', were counted as errors. Patient 1 made only one substitution error. Patient 2 made six substitution errors (one of which was the use of an English word for the object instead of the Dutch word). Patient 3 made 17 substitution errors, the only patient of the three who made a large number (43%) of this type of error. In all three patients, 197 stimulations were done at 77 sites, eliciting a total of 99 errors.

The results are depicted on the left hemisphere tracings for each patient in Fig. 1. These tracings were made directly from the venous phase of the angiograms; the sites were located in relation to the cortical veins, using colour photographs taken at the time of the language testing. The data provide an answer to the first question: in each case it was possible to find language functioning cortex throughout the extent of the left hemisphere exposure. Although this observation must be qualified by the fact that these are patients with long-standing epileptic foci, it seems reasonable to conclude that an individual's language system may occupy a very large extent of the lateral cortex, including the classical language zones derived from pooled data from many subjects. Indeed, our data show an even wider language zone than that proposed by Penfield and Roberts in that we find numerous language sites in the parietal operculum and mid-frontal and mid-parietal lobes. The answer to the second question seems to be no; the language function does not seem to be equally distributed throughout the left hemisphere. We repeatedly observed instances of a naming impairment on all stimulations at one site, and only partial or no impairments on all stimulations at an adjacent site, as represented in Fig. 1. The data suggest hypotheses of theoretical interest. If the patterns seen in these patients are indicative of language representation in non-epileptic left hemispheres, and there is no reason to assume that the non-epileptic cortex in these patients is abnormal, it is reasonable to infer that there is a marked degree of individual variation from one person to the next. If that inference is valid, it provides an obvious explanation for both the variety of aphasic symptoms and the variability of recovery of function which follow seemingly similar brain lesions.

## Infective *Theileria annulata* in the tick without a blood meal stimulus

THE agent of bovine tropical theileriosis, *Theileria annulata*, occurs in southern Europe, North Africa and most of Asia. The disease causes high mortality and reduced yield of meat and milk in the survivors. In enzootic areas theileriosis prevents the introduction of improved stock which are in most cases very susceptible. The work described here is part of a programme for improving the effectiveness of the vaccines now used for partial control of the disease. Theileriosis is transmitted in nature mainly by adult ticks that acquire their infection in the pre-imaginal stages. Adults become infective after feeding for a minimum of 2 d either on the susceptible bovine host or on a non-susceptible mammal like the rabbit<sup>1</sup>. As parasites can already be seen in the salivary glands of unfed adult ticks that are not infective<sup>2,3</sup>, it has been assumed that a blood meal provides the biological stimulus for the development of infectivity. In attempting to determine the factors other than feeding, that might stimulate the production of infective stage(s) of *T. annulata*, I have found that a temperature of 37 °C and a relative humidity (RH) of 95% is in itself sufficient to stimulate the production of infective parasite forms in infected adult *Hyalomma excavatum* ticks without the need for a blood meal.

Engorged nymphs of *H. excavatum* that were fed on a calf infected with *T. annulata* were maintained at 28 °C and 65% RH for 6 weeks and the adults that developed were kept for 3 months at 13 °C and 65% RH and served as the tick material for this study. When the adult ticks were allowed to feed for up to 2 d on susceptible calves, the animals were not infected, nor were calves which were injected with the homogenate of these ticks. Calves contracted theileriosis only after ticks had fed on them for 4-5 d, or after being injected with the homogenate of these ticks.

One hundred and thirty ticks from the same batch, enclosed in wire net containers covered with nylon net which prevented them from feeding, were placed in ear bags on a susceptible calf. After 2 d 65 of the ticks were transferred to the earbags on another susceptible calf for 24 h, during which time 38 ticks attached. The calf remained free of theileriosis. After 6 d the 53 confined ticks remaining on the initial calf were removed from the earbags, homogenised and injected into a fresh calf which died with fulminating theileriosis.

Unfed adult ticks were transferred from 13 °C and 65% RH to an incubator maintained at 37 °C and 95% RH for 6 d. The homogenate of 56 such ticks caused lethal theileriosis when injected into a susceptible calf. Unfed ticks which were kept at 13 °C, or ticks allowed to feed on calves for up to 2 d, did not transmit theileriosis either by bite or by needle inoculation.

From these results it seems that a temperature of 37 °C for several days, possibly coupled with high relative humidity, stimulated the non-infective particles of *T. annulata* in the salivary glands of the unfed *Hyalomma* ticks to become infective without the previous stimulation of feeding. These findings might explain the results of Mazlum<sup>4</sup> who was able to transmit *T. annulata* by injecting unfed infected adult *H. dromedarii* into cattle. Although Mazlum gave no explanation for his unexpected results, the fact that his ticks had been reared at 32 °C and 70-80% RH might have been a significant factor in the experiment.

The unsuccessful attempt by Nuttal and Hindle<sup>5</sup> to transmit *Theileria parva* by keeping unfed *Rhipicephalus appendiculatus* ticks at 37 °C for 3 d and feeding them on cattle for an additional 2 d, might be related to the species of ticks and the *Theileria* that they studied. The possibility that body temperature of the host, rather than tick feeding *per se* might be responsible for the appearance of infectivity in some tick-borne diseases is supported by the finding<sup>6</sup> that infective forms of *Babesia bovis* can be produced in unfed *Boophilus microplus* larvae by keeping them

at 37 °C. An elevation in temperature not only causes the appearance of infective particles, but also activates the ticks in general.

Failure to prevent theileriosis in hot climates by dipping cattle in acaricides every 3 d or even daily<sup>7</sup> might possibly be explained by the rapid appearance of infective particles in ticks exposed to high ambient temperatures, even before they have had a blood meal.

## Endosymbiont as supplier of ornithine carbamoyltransferase in a trypanosomatid

In spite of the widespread occurrence of intracellular bacteria-like symbionts in eukaryotic cells little is known about their function<sup>1-3</sup>. They are generally thought to offer some advantage to the host cell while benefiting from its 'hospitality', but their precise contribution is known in few cases. Flagellates that harbour endosymbionts provide excellent models for the analysis of this relationship. Three trypanosomatids, *Crithidia oncopelti*, *C. deanei* and *Blastocrithidia culicis* harbour endosymbionts whose bacteria-like nature has been confirmed morphologically and biochemically<sup>4-9</sup>. Unlike symbiont-free species<sup>10</sup>, those species do not require haemin for growth because the endosymbionts provide haemin-synthesising enzymes<sup>11</sup>. We now report that endosymbionts enable certain species of *Crithidia* to synthesise arginine from ornithine.

Although ornithine carbamoyltransferase (OCT) is characteristically absent from *Crithidia*, it is present in species harbouring symbionts (Table 1). OCT catalyses the first step in the synthesis of arginine from ornithine—the synthesis of citrulline from ornithine and carbamoyl phosphate. Because of its absence, endosymbiont-free *Crithidia* have an absolute growth requirement for arginine or

Table 2 Growth of three species of *Crithidia* in various media

Organism	<i>C. deanei</i>		<i>C. fasciculata</i>		<i>C. acanthocephali</i>	
Medium	GT	Cells per ml*	GT	Cells per ml	GT	Cells per ml
RDM	8	6 × 10 <sup>7</sup>	0	0	0	0
RDM+Orn	6.5	4 × 10 <sup>7</sup>	0	0	0	0
RDM+Cit	9	7 × 10 <sup>7</sup>	10	4 × 10 <sup>7</sup>	6.5	3.6 × 10 <sup>7</sup>
RDM+Arg	6.5	7 × 10 <sup>7</sup>	10	4.5 × 10 <sup>7</sup>	6.5	4 × 10 <sup>7</sup>

RDM, Roitman's defined medium<sup>17</sup> without arginine. RDM+Orn contains 3 mM L-ornithine; RDM+Cit contains 2.3 mM L-citrulline and RDM+Arg contains 2.3 mM L-arginine. GT is a rough calculation of the generation time in hours derived from inspection of growth curves.

\*Number of cells per ml, corresponding to measurements made at the stationary phase of the cultures, before cell decay.

citrulline. *Crithidia deanei* (Table 2) and *C. oncopelti*<sup>12</sup>, however, which have endosymbionts can grow in the absence of both amino acids, which indicates that they can synthesise citrulline through the mediation of OCT.

To investigate the role of the endosymbionts, we tested symbiont-free *C. deanei* and *C. oncopelti* for OCT (these strains are obtained by prolonged treatment with chloramphenicol (ref. 8 and personal communication from M. H. Mundin and I. Roitman)). Extracts of the strains showed no OCT activity (Table 1), suggesting that the symbionts provide OCT for *Crithidia*. But because chloramphenicol treatment is likely to affect the mitochondria<sup>13</sup>—reported to be the site of OCT in eukaryotes<sup>14-16</sup>—it is possible that the loss of OCT from *C. deanei* and *C. oncopelti* was due to impairment of protein synthesis in their mitochondria rather than to removal of symbionts.

Our efforts to isolate the symbionts and locate OCT within them were inconclusive—we produced subcellular

**Fig. 1** Histochemical demonstration of OCT in *Crithidia deanei* which contains an endosymbiont. Arrows indicate OCT reaction product; Es, endosymbiont; N, nucleus; fp, flagellar pocket; k, kinetoplast; b, blepharoplast; l, lipid droplet; m, mitochondrion. Pellets of log-phase cells were fixed for 30 min at 4 °C in glutaraldehyde (2.5% in 0.1 M cacodylate buffer, pH 7.2). After several rinses, pellets were incubated with 5 mM lithium carbamoyl phosphate; 3 mM lead nitrate; 5 mM trisodium citrate; 50 mM Tris-HCl, pH 8.5, and 10 mM L-ornithine for 20 min at 37 °C. In control preparations ornithine was omitted from the incubation mixture. After rinsing with Tris buffer, pellets were included in 3% agar. Small agar blocks were post-fixed in osmium tetroxide (1% in cacodylate buffer, pH 7.2) for 1 h at 4 °C. After dehydration the material was embedded in Epon, sectioned, stained with uranyl acetate and lead citrate and examined in a Siemens Elmiskop 101, 80 kV.

Table 1 Ornithine carbamoyltransferase in *Crithidia*

Organism	Enzyme specific activity
<i>C. fasciculata</i> (ATCC 11745)	0
<i>C. acanthocephali</i> (ATCC 30251)	0
<i>C. hamosa</i> (ATCC 30256)	0
<i>C. lucillae</i> (ATCC 14765)	0
<i>C. deanei</i> (ATCC 30255)	300
<i>C. deanei</i> without symbiont	0
<i>C. oncopelti</i> (ATCC 30264)	210
<i>C. oncopelti</i> without symbiont	0

Cells were grown in a undefined medium<sup>17</sup>. Cell homogenates were obtained by sonication. OCT was determined as before<sup>18</sup>. The assay mixture consisted of 40 mM Tris-HCl buffer, pH 8.5, 16.6 mM L-ornithine, 16.6 mM carbamoyl phosphate and 0.8 mg of enzyme protein in a final volume of 0.3 ml. After 15 min of incubation at 37 °C, reactions were stopped by addition of 5% trichloroacetic acid, and the citrulline formed was measured in the supernatant by the Archibald's method<sup>19</sup>. Results are expressed in nmol of citrulline per mg of protein per min. *Crithidia deanei* without symbiont was obtained from Drs I. Roitman and M. Mundin, University of Brasilia. *C. oncopelti* without symbiont was obtained from Dr K. P. Chang, Rockefeller University, through Dr Roitman.

fractions contaminated with mitochondrial fragments. The site of OCT was identified by electron microscopy. Log phase *C. deanei* and *C. oncopelti* were incubated with ornithine, carbamoyl phosphate and lead nitrate as before<sup>15</sup>. In this procedure the orthophosphate released during the OCT reaction is trapped *in situ* as a lead phosphate precipitate which can be visualised in electron micrographs. More than 40% of the cells examined showed a lead precipitate. When present, the precipitate was inside the symbiont and nowhere else in the cell (Fig. 1). No precipitate was found in preparations treated in the same way but without ornithine during incubation, nor in cells of the symbiont-free strains incubated with complete medium. Clearly OCT is localised in the endosymbiont and confers a nutritional advantage on its protozoan host.

We thank Dr H. Souza Santos for electron microscopy facilities; S. Galinari and C. L. Barbieri for assistance and Dr F. W. Wallace for reviewing the manuscript. This work was supported by funds from Conselho Nacional de Pesquisas and Fundação de Amparo a Pesquisa de São Paulo.

## Calcium mobilisation during reproduction in snail *Helix aspersa*

THE land snail *Helix aspersa* lays up to 100 eggs at a time, each with 0.6 mg of calcium in the form of calcite crystals. There is insufficient calcium in any part of the reproductive tract to account for this.

We have investigated egg shell calcification in *H. aspersa* and report here a substantial increase in blood calcium during this process while blood sodium and pH remain constant. Rapid calcium mobilisation from non-reproductive areas to the egg shell-forming uterus during this period results in a 70% elevation of the blood calcium concentration, involving an increase in both the bound and unbound fractions.

Of the 65 families of land pulmonate snails comprising about 15,000 species, members of at least 36 families lay eggs with coverings containing calcium carbonate<sup>1</sup>. The calcified deposits may take the form of individual crystals of calcite dispersed through a jelly coat as in *Helix* or a hard shell as in *Achatina* and *Strophocheilus*<sup>2</sup>. The egg shell of the snail has four features in common with that of the bird: (1) similarity of mineralogy, ultrastructural appearance and even size in such snails as *Strophocheilus*<sup>3</sup>; (2) deposition of the shell—concurrently with a small

Fig. 1 Calcium content of the eggs as a function of location in the uterus of a gravid *Helix aspersa*. The eggs are in single file with the sides of the uterine wall closely applied, though each egg seems to be free to rotate. As soon as an egg is released anteriorly a new one is formed at the posterior end in an assembly-line fashion. The ovotestis (OV) and albumen gland (Alb) are shown not to scale, at the posterior end of the uterus. The uterine wall is ciliated and shows strong peristaltic waves moving anteriorly; the vagina (V) is highly muscular and aids in the final extrusion of the eggs through the genital opening (Gen). The calcium content of the uterus after all of the eggs were removed was 0.27 mg. Inset shows a cross-section through a fully calcified egg; the calcium of the egg is in the form of individual calcite crystals dispersed throughout the egg jelly (J), which surrounds the albumen fluid (A) in which the ovum floats. (Correlation coefficient for regression line,  $r = 0.99$ .)

amount of organic material for the shell matrix—during passage along a tube lined with epithelium; (3) a high rate of calcium transport across the epithelium during shell formation; and (4) utilisation of the shell during embryonic development, in the snail for the shell, in the bird for the bones<sup>4</sup>. On examining several species of pulmonate snails, we found no storage of calcium in the reproductive tract sufficient to account for calcification of even a small percentage of the eggs of a single clutch. Apparently in the snail—as in the bird—calcium stored in other parts of the animal is mobilised and then passes in the blood to the reproductive tract where it is transported across the epithelium to the egg. We have examined egg-shell calcification in the snail *Helix aspersa* and have measured accompanying changes in the blood.

Typically 25-100 eggs are deposited in a single laying period (depending on the size and health of the animal), with an egg released approximately every 15 min. Each deposited egg contains about 0.6 mg calcium requiring a mobilisation of up to 60 mg calcium. The calculated rate of calcium transport across the uterine epithelium of *Helix aspersa* is approximately  $3 \times 10^{-8} \text{ mol cm}^{-2} \text{ h}^{-1}$ , and in another land snail examined, *Anguispira alternata*, the rate is about  $1 \times 10^{-8} \text{ mol cm}^{-2} \text{ h}^{-1}$ . This compares with a calculated rate of about  $2 \times 10^{-8} \text{ mol cm}^{-2} \text{ h}^{-1}$  for the hen<sup>5</sup>.

Eggs taken from various positions in a gravid uterus of *Helix* were found to have increasing amounts of calcium as they passed along the uterus (Fig. 1), and the amounts were in direct proportion to the distance traversed. This result demonstrates that over most of its length the various regions of the uterus have the same capacity to deposit calcium during passage of the egg. One should note that the uterine epithelium is rather closely applied to the eggs and the eggs are uniformly distributed in single file and

barely separated. There is almost no free fluid in the uterine lumen which can be aspirated so that the eggs are definitely not floating. Free calcite crystals were not present, indicating that crystal nucleation was initiated by the jelly which coats the egg.

During egg laying a dramatic increase in total blood calcium of nearly 70% was found. The elevation was due to an equivalent increase in both the bound and unbound fractions. The blood sodium level did not change significantly and the pH remained at the normal level of about 7.80 (Table 1).

We measured blood calcium levels during the reproductive period as a function of the number of eggs already calcified, and samples were also taken before and after the period of egg laying. Blood calcium suddenly rose from 5.89 mM to 9.93 mM with the onset of egg laying and was maintained for the entire duration of laying (calcification) and then dropped back to the normal level within a few hours after the last egg was released (Fig. 2).

Blood changes in *Helix* differ from those which occur during egg laying in birds in three significant respects: (1) in *Helix*, both bound and ultrafilterable calcium increased, whereas in birds only bound calcium associated with the transport of yolk proteins increases, (2) in *Helix*, blood calcium elevation takes place within several hours of the time of release of the first egg, whereas in birds this occurs several days before egg formation, and (3) in *Helix*, the blood pH is unchanged whereas in birds it is decreased (for a general review of avian egg laying, see ref. 6).

Two aspects of particular interest relating to the rapid mobilisation and utilisation of a relatively large amount of calcium during reproduction in snails are the sources of calcium and the characteristics of calcium transport

Fig. 2 Total calcium concentration of the blood of *Helix aspersa* at various stages of the egg-laying cycle. For each data point only a single sample of blood was taken from any given snail in order to avoid the lowering of calcium which otherwise may occur from trauma in laying animals (unpublished observations). Because of the great difficulty of predicting when an animal will initiate oviposition, only one point is available for the 6-h period before the appearance of the first egg. This sample represents blood calcium concentration only 2–3 h before egg shell calcification begins since it typically takes 3–4 h for a given egg to be fully calcified in passing through the entire length of the uterus. During egg shell calcification, represented on the graph by 0–11 h after the first egg laid, the blood calcium level was almost 70% higher than the normal level represented by the dotted line. This elevated blood calcium was maintained at a rather constant level as indicated by the regression equation for the line ( $y = 0.05x + 9.48$ ). Once the last egg was released, there was a sudden drop in the blood calcium level within 3 h and near normal values were reached a few hours later.

Table 1 Changes in blood of *Helix aspersa* during egg laying

	Normal	Egg-laying
*Calcium:		
total (mmol l <sup>-1</sup> )	5.89 ± 1.08 (14)	9.93 ± 1.29 (21)
% ultrafilterable	63 ± 3 (4)	61 ± 6 (4)
Sodium:		
total (mmol l <sup>-1</sup> )	65.7 ± 2.1 (9)	64.9 ± 3.4 (4)
pH	7.80 ± 0.03 (5)	7.79 ± 0.05 (6)

*Helix aspersa* snails were obtained from California and kept in the laboratory in standard light conditions in groups of 20, matched for approximate size. For all data on egg-laying snails, controls were animals from the same container in which the ovipositing snails were found, thus minimising variability in the degree of hydration, availability of food, and so on. All snails were kept in the active, non-aestivating state by providing high humidity, carrots, paper and calcium carbonate. Blood was taken by puncture of the vena pulmonalis immediately anterior to the auricle using a plastic syringe after the overlying shell area was quickly and gently removed. The pH of the blood was measured with a combination micro-glass electrode (MI Electrodes) on a Beckman expanded scale pH meter. Blood was drawn into a 1-ml plastic syringe; the hypodermic needle was immediately removed and the electrode inserted deeply into the syringe body containing the blood so that the tapered body of the electrode made an airtight fit with the syringe opening. Duplicate measurements were made within 45 s of sampling and no pH drift was observed over more than 5 min. (*Helix* blood freely exposed to air becomes more and more alkaline from loss of CO<sub>2</sub>.) For atomic absorption analysis of total blood calcium, a 10-μl sample of blood was diluted with 1.17% (w/v) La<sub>2</sub>O<sub>3</sub> in 5% (v/v) HCl (to prevent interference by elements such as aluminium, sulphate and phosphate) and then measured with a Perkin-Elmer 107 instrument. For sodium analysis, 10-μl samples of blood were diluted with distilled water and measured by flame emission spectroscopy. Blood was filtered at 15 pounds per square inch of N<sub>2</sub> or 2% CO<sub>2</sub>: 98% O<sub>2</sub> using a Clinical Ultrafiltration unit and an Amicon Diaflo Membrane of 1,000 MW cut-off. Ultrafiltration typically started with 1.0 ml of blood and no more than 50% of the fluid was allowed to pass through before the filtrate was collected. The amount of calcium in the filtrate is called unbound (mostly ionic and some complexed) and the remainder which is unfilterable is called bound. Values are mean ± standard deviation; sample size in parentheses.

## Inhibition of post-implantation development of mouse blastocysts *in vitro* after cyclophosphamide treatment *in vivo*

It has been widely believed that embryos, after treatment in the preimplantation period, either die before implantation or survive to term without being malformed<sup>1,2</sup>. But evaluation of the embryolethal effect of cyclophosphamide (CPA) before implantation in the rat has revealed effects of the early treatment on both embryo and mother around and after implantation<sup>3</sup>. Further investigations of the development of CPA-treated preimplantation rat embryos are impossible because rat embryos have not been cultured successfully *in vitro* beyond the time of implantation. On the other hand, routine culture of mouse embryos *in vitro* during the same period has been standardised<sup>4–6</sup>. Such systems are sufficiently sensitive for investigations of genetically-determined abnormalities<sup>7,8</sup> and the effects of *in vitro* exposure to ultraviolet and X irradiation<sup>9,10</sup>.

**Table 1** Cell number of mouse embryos at implantation (day 3), 24 h after CPA treatment of the mother

Developmental stage	Dose (mg kg <sup>-1</sup> )	Cell no. per embryo	No. of determinations
Morula (control)	0	25.9 ± 4.8	18
Blastocyst (control)	0	42.3 ± 11.3	25
Blastocyst (treated)	20	34.5 ± 13.0	17
Blastocyst (treated)	40	21.2 ± 3.7*	35
Blastocyst (treated)	60	18.4 ± 4.6†	43
Blastocyst (treated)	80	15.9 ± 2.8†	63

Determinations were performed at 1400 h on day 3 as described by Tarkowski<sup>19</sup>. At this time the number of embryos per mother ( $7.0 \pm 2.7$  in 148 determinations), the ratio blastocysts per morula ( $5/2$  in 148 determinations) and the mitotic index ( $4\% =$  cells in mitosis expressed as percentage of total cells of the embryo) were unaffected by any of the CPA doses tested. The cell numbers of morulae from CPA-treated mothers were affected in the same way as were blastocysts. The maternal LD<sub>50</sub> for CPA was 200 mg kg<sup>-1</sup>.

\*Significantly lower than cell number of control blastocysts at  $P < 0.01$  (Wilcoxon-test).

†Significantly lower than cell number of both control blastocysts and morulae at  $P < 0.01$  (Wilcoxon test).

<sup>3</sup>H-thymidine<sup>11</sup> and metabolic inhibitors<sup>12-14</sup>. To elucidate further the action of CPA on the embryos after maternal treatment during the pre-implantation period, we have used mouse blastocysts to repeat our studies with CPA in the rat, and we have also cultured mouse blastocysts for 120 h from CPA-treated mothers. With concentrations of CPA that did not affect the morphology of blastocysts from treated mothers but only the cell number at the time of implantation, development of the blastocysts *in vitro* was inhibited in a dose-dependent manner. This system holds promise as a test for putative teratogens.

To determine the rate of lethality at term after CPA treatment 24 h before implantation, groups of 10 pregnant NMRI mice (Zentralinstitut für Tierzucht, Hannover) received a single subcutaneous injection of CPA at 20, 40, 60 or 80 mg kg<sup>-1</sup> (a gift from Asta-Werke AG) on day 2 (day 0 = the day after the mating night). At term the resorption rates for the four doses tested were 35, 78, 100 and 100%. As described for the rat<sup>3</sup>, CPA did not reduce the number of embryos per mother before and around the time of implantation but significantly decreased the number of living embryos during organogenesis. As with the rat, no malformations could be detected and the somite numbers of treated mouse embryos surviving to organogenesis were significantly lower than for controls, indicating a retardation of development of about 24 h. This could have been explained by a delay in implantation and so the exact time of implantation was determined as before<sup>3</sup>. Again as in the rat, there was no indication of delayed implantation in the treated group. But at CPA concentrations of 40–80 mg kg<sup>-1</sup> (Table 1) the cell numbers of treated blastocysts were significantly smaller than those of controls and of the 20 mg kg<sup>-1</sup> group ( $P < 0.01$ , Table 1). At the highest CPA concentrations (60 and 80 mg kg<sup>-1</sup>) the cell numbers of blasto-

cysts were significantly smaller than those of normal morulae (Table 1). The considerably smaller cell numbers in blastocysts of treated animals is evidence for interference by CPA or one of its metabolites with embryonic development *in vivo* during the 24 h between days 2 and 3. At the same time there was histological evidence of a simultaneous inhibition of the decidual reaction of the uterus, as in the rat<sup>3</sup>.

Blastocyst transplantation has been used to show the maternal CPA treatment has a direct effect on pre-implantation rat embryos<sup>3</sup>. But with the mouse a different approach was used. Blastocysts treated *in vivo* were cultured *in vitro* in conditions such that differentiation usually proceeds as follows<sup>5</sup>: hatching from the zona pellucida after 36–48 h; attachment to the surface of the dish after 48 h, and outgrowth of three characteristic cell types—a trophoblast layer with trophoblast giant cells and an inner cell mass (ICM) consisting of two germ layers, ectoderm and endoderm—which is usually completed after 96–120 h. In our culture system embryos from CPA-treated mothers showed a dose-dependent inhibition of all steps of differentiation (Table 2). The percentage of embryos which underwent ICM differentiation into two germ layers was the most sensitive parameter. It was already significantly decreased at the lowest CPA concentration (20 mg kg<sup>-1</sup>), which had no significant effect on the cell number of the blastocysts (Table 1). Studies of treatment *in vitro* have revealed a higher sensitivity of the ICM cells than of trophoblast cells to substances which interfere with nucleic acid metabolism<sup>11-14</sup>.

Other investigators have reported morphological abnormalities in pre-implantation rat<sup>16</sup> and mouse<sup>17</sup> embryos after treatment of the mother. The morphology of early rat<sup>3</sup> and mouse embryos was not affected by CPA as far as blastulation is concerned. But the cell number of CPA-treated blastocysts was considerably smaller than normal. This effect of CPA on *in vivo* development of pre-implantation embryos between the eight-cell (day 2) and the blastocyst stage (day 3) indicates that blastulation, the first step of morphological differentiation, is not dependent on the presence of a particular number of cells and that cells, having lost the capacity to divide at a normal rate, can still form the blastocyst cavity. The effects of CPA on subsequent development *in vitro* might be explained by a retarded clearance of the alkylating agent or one of its metabolites from the blastocyst cavity<sup>3,18</sup>.

For the evaluation of the effects of teratogens on pre-implantation embryos, the *in vitro* approach has several advantages over embryo transfer for which success has been low and poorly reproducible<sup>18</sup>. The *in vitro* system requires fewer embryos, and it is faster and more precise because maternal factors and individual variations are not involved. It also gives clearcut dose-response relationships, which are usually not obtained when treated embryos are transferred<sup>19</sup>.

Our technique analyses only the direct effect of the teratogen on the embryo itself and does not allow an assessment of the influence of a disturbed maternal physiology on later development. The detection of maternal effects of the early treatment

**Table 2** Effect of cyclophosphamide (CPA) treatment *in vivo* on differentiation of mouse blastocysts *in vitro*

CPA dose (mg kg <sup>-1</sup> )	No. of blastocysts (100%)	Hatching (%)	Attachment and outgrowth (%)	Extensive trophoblast growth (%)	ICM 2 germ layers (%)
0	98	97	97	96	93
20	119	89*	91	82†	61‡
40	73	81	80*	71*	25†
60	135	62†	62*	50†	11†
80	50	30*	28‡	22‡	0†

Blastocysts were flushed from the uteri at 1400 h on day 3 (24 h after maternal treatment) and cultured in groups of 10 in medium NCTC-109 (Difco) supplemented with 10% foetal calf serum (Gibco) in plastic culture dishes at 37 °C in a humidified 5% CO<sub>2</sub> in air atmosphere, as described by Sherman<sup>5</sup>. Significance levels were determined by the  $\chi^2$  test separately for each step of differentiation by comparing the growth rates (as percentage of blastocysts cultured) at every CPA dose with the growth rate at the next lower CPA dose.

\*  $P < 0.05$ .

still requires transplantation experiments. In our studies with the rat we were able to show an inhibitory effect of early CPA treatment on the maternal environment by transplanting untreated embryos to treated and untreated pseudopregnant foster mothers<sup>3</sup>. Furthermore, transfer experiments are always necessary to check whether *in vitro* treatment during the preimplantation period is able to induce malformations at term<sup>18,20</sup>, especially because term malformations have been induced after transfer of preimplantation mouse embryos treated *in vitro* with the insecticide captan<sup>21</sup>.

## Carbon dioxide reversibly abolishes ionic communication between cells of early amphibian embryo

Low electrical resistance intercellular junctions have been found in a wide variety of adult tissues, both *in vivo* and in tissue culture<sup>1</sup> and in early embryos<sup>2</sup>. Vertebrate and invertebrate adult intercellular junctions are permeable to small ions and a variety of other molecules, of molecular weights possibly up to 1,000, as shown by the movement of tracers such as fluorescein<sup>3</sup> and transfer of nucleotides ('metabolic cooperation')<sup>3</sup>. In adult systems, such intercellular exchange is correlated with the presence of gap junctions<sup>4</sup>. In embryos, some form of specific junction is necessary to account for the observed electrical coupling after early cleavage stages<sup>5</sup> and the presence of gap junctions has been reported<sup>6-8</sup>. Since the low resistance intercellular pathway has been implicated in the control of spatial and temporal organisation during development<sup>9</sup>, the permeability of the embryonic junction assumes some importance. There is evidence suggesting that embryonic junctions are less permeable than adult junctions<sup>10-13</sup>, which we have recently confirmed<sup>14</sup>. Our experiments<sup>14</sup> suggested that there is selectivity in the gap junctional membrane which led us to predict that the junctional permeability would be sensitive to changes in intracellular pH. We present here results which confirm this prediction.

Electrical coupling between cells was measured in *Xenopus* embryos between the four-cell and mid-blastula stages. The embryos were continuously superfused with Holtfreter's solution (NaCl, 60 mM; KCl, 1 mM; CaCl<sub>2</sub>, 4 mM) buffered to

the required pH with 2 mM Tris hydroxymethylaminomethane or 10 mM ADA (*N*-(2-acetamido) iminodiacetic acid) (extracellular pH change) or 40 mM NaHCO<sub>3</sub>/CO<sub>2</sub> (intracellular pH change). Two glass intracellular microelectrodes (filled with 0.8 M potassium citrate) were inserted into one cell, one to record the membrane potential,  $E_1$ , and the voltage deflection,  $V_1$ , produced by a rectangular hyperpolarising current pulse ( $10^{-8}$  A, 1 s long, every 10 s) injected through the second microelectrode. A third microelectrode monitored the membrane potential in an adjacent cell,  $E_2$ , together with the voltage deflection produced by current flow through the intercellular junction,  $V_2$ . The ratio  $V_2/V_1$  gives a measure of the efficiency of electrical coupling between the cells. All parameters were displayed on an oscilloscope and slow writing chart recorder.

Extracellular pH changes between pH 5.8 and 7.5 had little effect on membrane potential, membrane resistance or electrical coupling. Intracellular pH was lowered by superfusing the embryo with a bicarbonate buffered Holtfreter solution saturated with 100% CO<sub>2</sub>; CO<sub>2</sub> crosses the membrane and forms carbonic acid which liberates H<sup>+</sup>, so lowering pH<sub>i</sub> (ref. 15). Figure 1 shows the effect of exposing a 64-cell embryo to 100% CO<sub>2</sub>; by contrast with an extracellular pH change, this brought about a rapid increase in junctional resistance, culminating in complete uncoupling of adjacent cells.

Table 1 summarises experiments on embryos between the 4-cell and blastula stages of development. In four- and eight-cell embryos lowering the intracellular pH had no effect on the coupling ratio  $V_2/V_1$ . Treatment with CO<sub>2</sub> produced a change in membrane potential, of variable magnitude and sign, at all stages of development tested, suggesting that depolarisation is not the cause of uncoupling; the membrane potential changes may be caused by an effect of CO<sub>2</sub> on the permeability of non-junctional membranes. When CO<sub>2</sub> uncoupled the cells there was invariably a concomitant rise in input resistance. Since CO<sub>2</sub> caused little change in resistance at the eight-cell stage it is unlikely that the uncoupling is brought about by the earthing of restricted extracellular current pathway normally responsible for current flow from one cell to the next. The most reasonable conclusion is that current flow from one cell to the next is largely mediated by a specialised intercellular pathway, whose permeability is greatly reduced when the embryo is

Fig. 1 Exposing a 64-cell embryo to 100% CO<sub>2</sub>. The pen record (B) begins with the embryo in Holtfreter solution at pH 7.5. The membrane potential was -17 mV and the coupling ratio, 0.9. Oscilloscope records of the individual electrotonic potentials  $V_1$  and  $V_2$  are shown above (A). At the arrow a Holtfreter solution buffered with 40 mM NaHCO<sub>3</sub> and equilibrated with 100% CO<sub>2</sub> (at pH 6.5) was admitted to the bath. The membrane potential in cell 2 decreased by 10 mV while the input resistance, recorded in cell 1, increased; at the same time electrical coupling between the cells disappeared. After 2.5 min uncoupling was complete, only capacitative artefact remains on the  $E_2$  trace. A (b), confirms the complete absence of an electrotonic potential in the adjacent cell. The return to Tris-buffered solution rapidly restored both membrane potential and electrical coupling (c).

**Table 1** Uncoupling induced by CO<sub>2</sub> at different developmental stages

	Initial resting potential (mV)	Potential during CO <sub>2</sub> (mV)	Final membranal potential (mV)	Effect of CO <sub>2</sub> on coupling
Stage 3 (4 cell)	20 11	6 0	8 0	None None
Stage 4 (8 cell)	11 11 10	5 6 10	5 8 13	None Partial uncoupling None
Stage 5 (16 cell)	26 16 18	10 3 5	18 15 18	Uncoupling Uncoupling Uncoupling
Stage 6 (32 cell)	21 10 8	0 0 0	24 8 10	Uncoupling Uncoupling Uncoupling
Stage 6½ (64 cell)	40 20 17 —	18 3 7 3	20 10 14 30	Uncoupling Uncoupling Uncoupling Uncoupling
Stage 7 (mid blastula)	— 20 25	3 5 5	33 25 30	Uncoupling Uncoupling Uncoupling

Membrane potential recorded at  $V_2$  electrode; all potentials negative with respect to zero. At 4- and 8-cell stage measurements made across first cleavage plane. Uncoupling means  $V_2/V_1$  falls to zero. No effect means normal  $V_2/V_1$  ratio (between 0.8 and 0.9).

exposed to CO<sub>2</sub>. The insensitivity of early cleavage stage embryos may reflect incomplete cleavage (the cells cleave every 20 min), or a change in membrane properties as the embryo enters the morula stage. In all other cases CO<sub>2</sub> completely abolished current flow from one cell to the next. This was always rapid and totally reversible.

Measurements of intracellular pH (using pH-sensitive micro-electrodes<sup>13</sup>) (in collaboration with R. C. Thomas) showed the pH to fall from a resting value of 7.7 to between 6.4 and 6.2 on exposure to 100% CO<sub>2</sub>. The intracellular pH change followed the same time course as the uncoupling. Extracellular pH changes between 5.8 and 7.5 had no effect on the intracellular pH.

The simplest interpretation of these results is that the effect of CO<sub>2</sub> treatment on electrical coupling between cells of the early *Xenopus* embryo is mediated by the low intracellular pH. An effect of anoxia is unlikely, since early amphibian embryos are notoriously resistant to oxygen lack<sup>14</sup> and we have found that treatment with 60% CO<sub>2</sub>: 40% O<sub>2</sub> is equally effective. It has been proposed that the permeability of the intercellular junction is controlled by the intracellular concentration of ionised calcium<sup>15</sup>. Since Meech and Thomas<sup>17</sup> have recently demonstrated that intracellular injection of Ca<sup>2+</sup> leads to a concomitant fall in intracellular pH, the possibility that a fall in intracellular pH rather than a rise in free Ca<sub>i</sub> was responsible for uncoupling observed in experiments such as those on the *Chironomus* salivary gland of Rose and Loewenstein<sup>18</sup> must now be considered. The question whether in our experiments the increase in intracellular H<sup>+</sup> displaces calcium from intracellular binding sites, so that intracellular calcium exerts the ultimate control remains open, although there are arguments against this possibility. We have injected iontophoretically into *Xenopus* embryo cells at the 64-cell stage sufficient calcium to bring about profound contracture of the contractile cytoplasm beneath the plasma membrane (making the free calcium level likely to be well above 10<sup>-8</sup> M (ref. 6)) without affecting the intercellular flow of current. 100% CO<sub>2</sub> did not produce any sign of contraction of the contractile cortex, despite its efficacy as an uncoupling agent, suggesting that no massive release of

calcium occurs. We therefore consider that a rise in Ca<sub>i</sub> was not primarily responsible for the uncoupling seen in *Xenopus* embryos on lowering intracellular pH.

The results described here open up a number of interesting possibilities. First it may be that the intracellular pH, rather than intracellular calcium, controls junctional permeability and similar experiments on the *Chironomus* salivary gland become important. Second, an increase in intracellular pH could cause a rise in junctional permeability and may provide a way of making the poorly permeable embryonic junction more like its adult counterpart. Finally, despite the difficulty of eliminating possible side effects of CO<sub>2</sub> treatment, our experiments offer, for the first time, the opportunity to test whether electrical coupling plays an essential role during development, as it should now be possible to reversibly uncouple the embryonic amphibian system and observe the developmental consequences. Experiments to answer these questions are already in progress.

## Unique cytoplasmic phosphoproteins are associated with cell growth arrest

THE intracellular molecular processes responsible for the regulation of animal cell growth are not understood. Cyclic AMP has been implicated in the arrest of cell growth (see ref. 1 for review) and it has been postulated that all cyclic AMP effects are mediated through protein kinase<sup>2</sup>. Insel *et al.*<sup>3</sup> have demonstrated with mutants that a cyclic AMP-dependent protein kinase mediates the growth inhibitory effect of cyclic AMP in S49 cells. Maller and Krebs<sup>4</sup> have established that the catalytic subunit of cyclic AMP-dependent protein kinase was both necessary and sufficient to block progesterone induced meiotic cell division in *Xenopus* oocytes. The above observations suggest that a high steady-state level of a phosphoprotein which is subject to control by cyclic AMP-dependent protein kinase functions in a regulatory manner to arrest cell growth. Since cyclic AMP-dependent protein kinases are found predominantly in the cytoplasm, we investigated the phosphorylation of cytoplasmic phosphoproteins and report here that quiescent cell cytosol contains several unique phosphoproteins.

The cell line used in this study was baby hamster kidney (BHK)<sub>21</sub> clone 13. Logarithmically growing cells were brought to quiescence by incubation in serum-deficient medium (0.1% calf serum in Dulbecco's modified Eagle's medium) for 40 h.

**Fig. 1** *In vitro*-labelled cytoplasmic phosphoproteins in quiescent and proliferating cells. Cytosol was prepared from quiescent (Q) and proliferating (P) BHK cells in the following manner. Cells on 100-mm dishes were washed twice with phosphate-buffered saline and scraped from the plate with a rubber policeman. The cells were centrifuged at 600g and the cell pellet washed twice more with phosphate-buffered saline. The cell pellet was resuspended in homogenisation buffer (10 mM HEPES (pH 7.4), 5 mM  $MgCl_2$ , 25 mM KCl), and cells were disrupted in a Potter-Elvehjem homogeniser. The homogenate was spun at 100,000g for 30 min and the supernatant (cytosol) dialysed for 12 h against the reaction buffer (100 mM NaCl, 20 mM HEPES (pH 7.2), 10 mM  $MgCl_2$ , 1 mM EGTA) at 4 °C. Inclusion of a protease inhibitor, phenylmethyl sulphonyl fluoride, in the dialysis buffer had no effect on the electrophoretic protein profile nor on phosphorylation. Cyclic AMP-dependent protein kinase activity was examined before and after dialysis using exogenous histone as substrate: no activity was lost in either cytosol preparation during dialysis. Cytosol protein concentration was adjusted to 2.5 mg protein per ml and theophylline (2 mM), NaF (10 mM), dithiothreitol (1 mM) and cyclic AMP (1  $\mu$ M, when present) were added. The reaction was initiated by the addition of  $\gamma$ - $^{32}P$ -ATP (2  $\mu$ M, 1,000–3,000 Ci mmol $^{-1}$ ) and was run for 5 min at 30 °C. The kinetics of phosphorylation revealed that maximum incorporation of  $^{32}P$  occurred by 5 min in both quiescent and proliferating cytosol proteins. The reaction was terminated by addition of electrophoresis sample buffer (1% SDS, 1% mercaptoethanol, 50 mM Tris pH 6.8, final concentrations), and boiling for 1 min. Proteins were separated by SDS-polyacrylamide slab gel electrophoresis<sup>5</sup>. Gels were stained with Coomassie blue in 45% methanol and 7.5% acetic acid, destained and dried. Phosphoproteins were visualised by exposure of the dried gel to X-ray film. Molecular weights of phosphoproteins were estimated by comparison with standard proteins ( $MW \times 10^{-3}$  shown below autoradiogram) as described by Weber and Osborn<sup>7</sup>. cAMP, cyclic AMP.

At this point over 95% of the cells were arrested in G<sub>1</sub> phase of the cell cycle as determined by flow microfluorimetry.

Cytoplasmic extract was prepared from quiescent and proliferating cells and subjected to *in vitro* phosphorylation with  $\gamma$ - $^{32}P$ -ATP. The cytosol proteins were then separated by sodium dodecylsulphate (SDS)-polyacrylamide slab gel electrophoresis, and the phosphoproteins were identified by exposing the dried gel to X-ray film. Approximately 20 phosphoproteins were identified in cytoplasmic extracts from both quiescent and proliferating cells in the absence of cyclic AMP; most of the phosphoproteins in quiescent and proliferating cytosol were identical and phosphorylated to the same extent (Fig. 1). But a protein of molecular weight (MW) 76,000 was consistently phosphorylated only in cytosol from quiescent cells. In proliferating cell cytosol a protein of MW 96,000 was more intensely phosphorylated than in quiescent cytosol (Table 1). The pattern of Coomassie blue stained proteins in quiescent and proliferating cells was identical.

Incubation of the cytosols with cyclic AMP resulted in several striking differences in the phosphoprotein profile. Five proteins were consistently phosphorylated only in quiescent cell cytosol in the presence of cyclic AMP (Figs 1 and 2). These proteins included two that were larger than 220,000 (largest band seemed to be a doublet), and proteins of MW 140,000, 76,000 and 66,000. Surprisingly, cyclic AMP always inhibited the phosphorylation of the 96,000 MW protein by 40% (Table 1). The presence of cyclic AMP stimulated the phosphorylation

of only one protein (160,000 MW) unique to the proliferative growth state. All other cyclic AMP-stimulated phosphoproteins seemed to be in common with quiescent cell cytosol. Cyclic AMP also decreased phosphorylation of the 96,000 MW protein in proliferating cytosol (Table 1). Similar cyclic AMP effects were observed at concentrations of cyclic AMP from 0.1 to 10  $\mu$ M.

The same cyclic AMP-dependent phosphoproteins were observed when BHK cells were growth-arrested by isoleucine deprivation or serum deprivation, indicating that these phosphoproteins are associated with the quiescent state induced by two different conditions and are not simply the result of low serum in the culture medium.

The  $^{32}P$ -labelled bands in Fig. 1 were not destroyed by RNase, DNase, hot trichloroacetic acid or 1 M hydroxylamine. Protease treatment before electrophoresis destroyed all labelled bands as did 0.4 M NaOH at 37 °C for 18 h, indicating that the  $^{32}P$  bands represent phosphate covalently esterified to serine or threonine residues in cytosol proteins.

Wehner *et al.*<sup>6</sup> have reported that density-inhibited cells contain a 110,000 MW protein which is phosphorylated in the absence of exogenous cyclic AMP. We could not observe this

**Fig. 2** Quantitation of  $^{32}P$  incorporated into cytoplasmic phosphoproteins in quiescent and proliferating cells. The dried gel from the experiment depicted in Fig. 1 was cut into 2-mm slices and counted in a liquid scintillation counter. *a*,  $^{32}P$  incorporated into resting cell cytosol proteins in the presence (—) or absence (---) of cyclic AMP. *b*,  $^{32}P$  incorporated into proliferating cell cytosol proteins in the presence (—) or absence (---) of cyclic AMP.

**Table 1** Phosphorylation of the 96,000 MW protein in quiescent and proliferating cells and the effect of cyclic AMP

Source	<sup>32</sup> P c.p.m. per band*
Resting cell cytosol	8,490
Resting cell + cyclic AMP	5,022
Proliferating cell cytosol	27,689
Proliferating cell + cyclic AMP	21,920

Each cytosol was adjusted to 2.5 mg of protein per ml and subjected to phosphorylation conditions as described in Fig. 1. Exactly the same amount of protein was applied to the gel in each case. After the gel was dried and exposed to X-ray film, the 96,000 MW region was cut from the gel and counted in a liquid scintillation counter.

\*Average of two experiments

phosphoprotein in our studies: this may be because different cell lines were used in the two studies but important methodological differences may also explain this discrepancy. First, we used culture conditions in which the cells at the time of the experiment were at the same density but the growth state was modulated by the presence or absence of serum in the culture medium. Second, we dialysed the cytosol against the reaction solution before carrying out *in vitro* phosphorylation reaction. This brings the cytosol to specified pH and ion concentration and permits the study of cyclic AMP effects on phosphorylation. Wehner *et al.*<sup>6</sup> did not dialyse the cell extract and found no cyclic AMP effects that could be related to growth. Third, we used homogenisation in a Potter-Elvehjem homogeniser to disrupt cells and prepare cytosol while Wehner *et al.*<sup>6</sup> used sonication, a technique that damages membranes and disrupts cellular organelles, and carried out phosphorylation reactions on the total cellular sonicate. Thus, the relationship of the 110,000 MW phosphoprotein of Wehner *et al.*<sup>6</sup> to our data is not clear.

Results from several studies (reviewed in ref. 1) have established that elevated cyclic AMP is associated with the arrest of cell growth. The data presented here establish that quiescent cells consistently contain five unique phosphoproteins, four of which are phosphorylated only in the presence of cyclic AMP, and provide a possible mechanism by which cyclic AMP can control animal cell growth. The phosphoproteins may function as regulatory proteins to stop cell growth and maintain a G<sub>1</sub> block. Addition of mitogenic substances such as serum, which lower cyclic AMP<sup>8</sup>, to the culture medium would result in the dephosphorylation of the particular phosphoprotein(s) which maintains the G<sub>1</sub> block and thus, transit through G<sub>1</sub> is permitted. Other proteins may have to be phosphorylated or dephosphorylated at other points in the cell cycle to regulate progress through the cycle. An example of this would be the 96,000 MW protein which we have found to be intensely phosphorylated in proliferating cells by a cyclic AMP-independent protein kinase. The fact that cyclic AMP inhibits the phosphorylation of this protein is consistent with its possible role in promoting cell growth.

## Tumour-dormant states established with L5178Y lymphoma cells in immunised syngeneic murine hosts

THE tumour-dormant state is one in which tumour cells persist in a clinically normal host for prolonged periods. Tumour dormancy is a potentially unstable state and may culminate in either destruction of all tumour cells or death of the host due to tumour outgrowth. We report here two systems in which tumour-dormant states could be established with transplantable lymphoma cells inoculated into specifically immunised syngeneic murine hosts. A high percentage of mice kept for long-term observation eventually developed tumours and in both systems, tumour cells could be isolated from mice during a prolonged period of clinical normality.

There are many reports describing the recurrence of solid tumours and leukaemias years after apparently successful treatment of the primary neoplasia<sup>1-3</sup>. These reports suggest that residual tumour cells can persist in a dormant state during periods of prolonged clinical remission, but do not rule out *de novo* recurrence of the same type of cancer due to a long lasting predisposition of the patient's cells to malignant transformation.

Since Fisher and Fisher's first report on tumour dormancy in rats<sup>4</sup>, only a few animal models have been developed for the study of this state<sup>5-8</sup>. Tumour dormancy in experimental animals may, however, be a frequent occurrence which goes unrecognised because experiments are usually terminated before tumour dormant cells emerge to produce overt tumours. We wish to make others aware that resistance of mice to tumour-cell challenge may be associated with prolonged tumour dormancy rather than tumour cell rejection.

In our experiments, we used the methylcholanthrene-induced lymphoma, L5178Y, an immunogenic, weakly metastatic tumour of DBA/2 origin<sup>9</sup>. In the first system, DBA/2 mice were immunised by intraperitoneal (i.p.) injection of 10<sup>7</sup> mitomycin C-treated L5178Y cells and thereby protected against the rapid outgrowth of live tumour cells inoculated i.p. 10 d later. Long-term observation of these mice revealed that 55-95% eventually developed tumours, some as late as 5 months after cell inoculation. In the experiment described here, immunised mice were killed on selected days after L5178Y cell challenge and attempts made to recover tumour cells from the peritoneal cavity and the spleen by *in vitro* culture. Additional mice from the same group were observed for extended periods for delayed tumour cell outgrowth. All non-immunised DBA/2 mice died of tumour growth within 25 d of i.p. inoculation of 5 × 10<sup>4</sup> live L5178Y cells, whereas no deaths occurred in the immunised, challenged mice until day 60, and by day 210, 93% of the mice had died of tumours (Fig. 1). Table 1 shows that tumour

**Fig. 1** DBA/2 females (8-10 weeks) were immunised by intraperitoneal (i.p.) injection of 10<sup>7</sup> mitomycin C-treated L5178Y cells. Control mice received an equivalent amount of PBS. All mice were given 5 × 10<sup>4</sup> L5178Y cells i.p. 10 d later. Shaded histogram, controls; open histogram, treated animals.

**Table 1** *In vitro* isolation of tumour cells from clinically normal mice previously immunised with mitomycin C-L5178Y cells

Time after tumour cell challenge (d)	Site of tumour cell isolation (No. mice with tumour cells/total no. mice tested)	
	Peritoneal cavity	Spleen
30	3/5	0/5
49	2/2	1/2
55	4/7	3/7
Total	9/14	4/14

Clinically normal mice (see text) were killed at the times shown. Their peritoneal cells and spleens were collected, washed and single cell suspensions of each were placed into culture at various concentrations and observed for 14 d. Cultures were judged positive for tumour cell outgrowth if increasing numbers of large lymphoblastoid cells appeared and continued to proliferate when transferred into new culture vessels.

cells could be isolated from cultures of peritoneal cavity cells and of spleen cells removed from these mice during the period when they were clinically normal. (Mice were judged to be clinically normal if total body weight did not exceed 30 g; the abdomen did not seem distended; macroscopic tumour foci were not visible following killing; and the total peritoneal cell count did not exceed  $1 \times 10^7$  cells.) The criterion for isolation of tumour cells *in vitro* was the appearance of increasing numbers of large lymphoblastoid cells which continued to proliferate following transfer into new culture vessels. These cells, when inoculated i.p. into normal DBA/2 mice, routinely produce ascitic tumours within 30 d, indicating that tumour cells recovered from dormant mice retain their tumorigenicity in normal syngeneic animals. An attempt was made to determine the period of persistence of tumour cells in a dormant state and we found that they could be recovered from the peritoneal cavity of clinically normal mice as long as 380 d after original tumour cell challenge.

To avoid the possible artefacts that occur when immunisation and tumour challenge are both given intraperitoneally, we used a sinecomitant immunisation procedure in our second system. DBA/2 mice were injected subcutaneously with  $1 \times 10^6$  L5178Y cells and 10 d later the small (1 cm) tumour nodules were excised. Such control mice remained free of tumour throughout a 160-d observation period, and no tumour cells could be isolated from their spleen or peritoneal cells, indicating that excision of the nodule had been complete and that no metastasis had occurred from the primary site of implantation. Excision of the tumour nodule protected mice against the rapid outgrowth of  $5 \times 10^4$  L5178Y cells inoculated i.p. 7 d later (Fig. 2); however, most of these challenged mice eventually developed tumours by day 160. Tumour cells could be isolated from the peritoneal cavity of many

**Fig. 2** DBA/2 females (8–10 weeks) were immunised by implantation of  $10^6$  live L5178Y cells subcutaneously on the ventral surface. Tumour nodules were removed surgically 10 d later, and mice were challenged 7 d later by i.p. inoculation of  $5 \times 10^4$  L5178Y cells. Control animals received PBS subcutaneously and  $5 \times 10^4$  L5178Y cells intraperitoneally at the appropriate times. Shaded histogram, controls; open histogram, immunised animals.

of the immunised and challenged mice while they were clinically normal (Table 2).

Results of experiments in both systems show that specific immunisation does not lead to complete elimination of all challenge tumour cells, but rather results in the establishment of a tumour-dormant state in a high percentage of animals. During this dormant state, tumour cells which were restrained from outgrowth *in vivo* grew out rapidly when transferred to *in vitro* culture. Although immunisation with mitomycin C-treated or X-irradiated tumour cells<sup>10,11</sup>, or with live tumour cells which were subsequently removed<sup>12,13</sup>, has previously been reported to protect mice against the rapid growth of a tumour cell challenge, in none of these studies were the mice observed long enough for dormant cells to emerge.

Essential to the tumour-dormant state is *in vivo* restraint of tumour cell outgrowth. In our systems a single surviving L5178Y cell doubling unrestrained at its normal *in vivo* rate ( $\sim 11$  h) can produce a pronounced ascites within 30 d—an interval which represents a small fraction of the observed tumour-dormant period of clinical normality. The possible mechanisms of tumour cell growth restraint *in vivo* include: continuous tumour cell division with concurrent tumour cell destruction; cytostatic effects which greatly prolong the *in vivo* population doubling time of the

**Table 2** *In vitro* isolation of tumour cells from clinically normal mice previously immunised by L5178Y tumour nodule formation and excision\*

\*See legend to Table 1.

tumour cells; immunoselection of a tumour cell subpopulation which grows more slowly than the original population; and sequestration of residual tumour cells in anatomical sites where they can escape destruction but still be inhibited in their division rate. Eccles and Alexander<sup>5</sup> showed that tumour metastases may be maintained in a dormant state by immunological mechanisms, since immunosuppressive measures resulted in outgrowth of tumour cells.

The rapid *in vitro* outgrowth of tumour cells from peritoneal and spleen cell cultures prepared from tumour-dormant mice suggests that effector cells or soluble factors that suppress tumour cell proliferation *in vivo* may be either lost or inoperative after removal from the animal. A related observation may be the "escape from cytostasis" described by Remington and coworkers<sup>14</sup>. They found that activated macrophages could inhibit <sup>3</sup>H-thymidine uptake by tumour cells for only 24 h after *in vitro* challenge, with renewed uptake of labelled thymidine observed thereafter. A similar tumour escape from host cytostatic mechanisms may be responsible for *in vitro* tumour cell outgrowth in our models.

Absolute identification of the origin of tumour cells emerging after the dormant period is very difficult in our syngeneic systems. We have, however, observed that tumour cells which emerged in dormant mice 80 d after challenge grow out rapidly when inoculated into normal mice but fail to grow out when inoculated into L5178Y-immunised mice, indicating that the emerging cells express L5178Y tumour-associated transplantation antigens. Additionally, DBA/2 mice have an extremely low incidence of spontaneous lymphomas and although electron microscopy of

L5178Y cells reveals the presence of a C-type virus, no infectious virus could be demonstrated by either S+L- or XC assays, and homogenates of L5178Y cells were not tumorigenic (unpublished results).

The two murine systems reported here are now being analysed to elucidate the mechanisms involved in the establishment and maintenance of the tumour-dormant state, with a view to identifying those events which lead to breakdown of the tumour-dormant state and development of overt neoplasia.

## Post-infection genetic resistance to avian lymphoid leukaemia resides in B target cell

NEOPLASMS in which the target for transformation is a B-dependent lymphoid cell include Burkitt's lymphoma<sup>1</sup> and chronic lymphocytic leukaemia<sup>2</sup> of man, bovine leukaemia<sup>3</sup> and lymphoid leukaemia in chickens<sup>4-11</sup>. Inherited resistance to the development of tumours may involve at the first level, a resistance of all cells in the body to infection by tumour viruses or, at the second level, a failure of the tumour to develop or progress in virus-infected animals<sup>12-14</sup>. In mice, the *H-2*-associated resistance to leukaemia is at the second level and is probably an example of immune surveillance, in which the immune system eliminates or prevents the multiplication of nascent malignant cells<sup>14-16</sup>. Possible effector mechanisms for immune surveillance which have been described include cytotoxic cells<sup>17</sup>, antibody<sup>18</sup> or non-lymphoid cells<sup>19,20</sup>. An alternative to immune surveillance is that genetic resistance may be expressed directly by the target

cells, involving resistance either to viral infection<sup>21</sup> or to malignant transformation. We have used transfers of bursal cells from genetically resistant chickens into bursa-lymphocyte-depleted genetically susceptible chickens, and vice versa, to show that genetic resistance to lymphoid leukaemia resides in the bursal target cell, and that neither non-B cells nor cooperation between non-B cells and B cells has a role in this resistance.

The genetically resistant chicks were from East Lansing inbred line 6 subline 1 (R), and the genetically susceptible chicks from the F1 cross of East Lansing inbred lines 15 subline 1 and 7 subline 2 (S)<sup>22</sup>. These chicks are semi-allogeneic, having major histocompatibility genotypes *B<sup>2</sup>/B<sup>1</sup>* and *B<sup>2</sup>/B<sup>1</sup>*, respectively. Thus, it was necessary for bursal cell transfers to be made into recipients at 3 d of age, that is, within the tolerance-responsive period, in order to ensure successful bursal reconstitution in the histoincompatible transfers<sup>23</sup>. In other respects the transfers were as previously described for syngeneic cells<sup>7</sup>. Recipient chicks were treated with three doses of 4 mg cyclophosphamide (Cytosan, Mead Johnson) on days 0, 1, and 2 after hatching and received intravenous injections of bursal lymphoid cell suspensions from 10-d-old donors on day 3. The doses were  $1.15 \times 10^8$  cells per recipient from susceptible donors, but only  $7 \times 10^7$  cells per recipient from resistant donors, since these donor chicks from line 6<sub>1</sub> had exceptionally small bursas. Groups of untreated and cyclophosphamide-treated chicks served as non-transferred controls. Within 1 d of the transfers, all chicks were infected intravenously (i.v.) with  $>10^4$  tissue culture infective doses of avian leukaemia virus (RAV-1), and were vaccinated against Marek's disease by intramuscular inoculation with approximately 2,000 plaque-forming units of turkey herpesvirus vaccine<sup>7</sup>. Tests for humoral immune function were performed at 16 weeks by inoculating killed *Brucella abortus* and sheep erythrocytes i.v. and bleeding for serum 1 week later<sup>7</sup>. All birds dying during the experiment were necropsied and survivors were killed and examined for lymphoid leukaemia at 33 weeks of age, using both gross and histopathological study. Table 1 includes the pooled data from two replicate experiments performed 1 month apart in which the results were similar.

Regardless of recipient genotype, cases of lymphoid leukaemia occurred only in chickens receiving bursal cells from donors of susceptible genotype (Table 1, groups 1 and 2), and no cases resulted from transfer of bursal cells of resistant genotype (groups 3 and 4). The incidence of lymphoid leukaemia in the successfully reconstituted recipients of susceptible-type bursal cells (groups 1 and 2) was lower than in the untreated susceptible controls (group 8). Successful B-cell functional reconstitution with bursal cells was achieved in almost all the syngeneic transfers (groups 2 and

Table 1 Effect of bursal cell transfer on antibody response and lymphoid leukaemia development in cyclophosphamide-treated chicks

Group	Donors Phenotype	Recipients		No. tested	No. (%) responders*	Antibody and LL among responders		
		Phenotype	Treatment			SE Titre+	Ba Titre+	%LL†
1	S	R	CY	39	15 (38)	10.4	10.3	50
2	S	S	CY	32	32 (100)	11.5	11.3	44
3	R	S	CY	20	10 (50)	8.0	6.8	0
4	R	R	CY	22	21 (95)	10.9	8.8	0
5	None	R	CY	26	0	—	—	0
6	None	S	CY	29	0	—	2.6	0
7	None	R	None	26	26 (100)	11.6	11.2	4
8	None	S	None	18	18 (100)	11.9	10.4	100

Groups of genetically resistant (R) or susceptible (S) recipients were treated with cyclophosphamide (CY) on days 0-2 after hatching and received i.v. transfers of bursal cells 3 d after hatching from 10-d-old R or S donors. At 16 weeks, all birds were injected i.v. with *Brucella abortus* (Ba) and sheep erythrocytes (SE), and bled for serum 1 week later. Results of two replicate experiments were similar and are pooled.

\*Responders to both SE and Ba. In group 6, 12/29 responded to Ba with very low titres (1-5 log<sub>2</sub>).

†Mean log<sub>2</sub> titre of responders to each antigen.

‡LL, lymphoid leukaemia.

4), as shown by the incidence and titres of antibody responses. Reconstitution was less effective in the semi-allogeneic transfers, being 50% in the histocompatible group (R→S) and 38% in the converse histoincompatible group 1. Nevertheless, the results for lymphoid leukaemia incidence, based on successfully reconstituted chickens only, were clear-cut. Similar results were obtained in experiments in which susceptible chicks were reconstituted with syngeneic bursal cells<sup>7</sup>. It seems that the chance of bursal cells becoming transformed by leukaemia virus may be somewhat reduced in some reconstituted chicks, even though there are sufficient stem cells available to repopulate the antibody-forming system.

In confirmation of our previous findings<sup>7</sup>, the effect of cyclophosphamide treatment was to lower lymphoid leukaemia incidence from 100% to zero in susceptible chickens (groups 6 and 8), accompanied by a near-total suppression of humoral immune responses. The very low incidence of lymphoid leukaemia in resistant chickens (4%, group 7) was reduced to zero by cyclophosphamide treatment (group 5), with total loss of antibody responses.

From the clear-cut evidence that differences in lymphoid leukaemia incidence between groups of birds with successful restoration of the bursal system are associated with the genotypes of the donors rather than of the recipients, we conclude that resistance to lymphoid leukaemia of line 6<sub>1</sub> chickens is conferred on them by the bursal cells and not by other cellular elements of the immune system such as thymic or thymus-derived cells or non-lymphocytes. Although it is possible that this resistance may reside in B cell-mediated specific humoral immunity alone, as may occur in feline leukaemia<sup>18</sup>, it seems more likely that an intrinsic inability of the bursal target cell to become infected or transformed is the major factor.

## Two mechanisms of migration inhibition factor induction by tumour antigens

EVIDENCE has accumulated which stresses the importance of lymphokines in cell-mediated immunity both *in vivo* and *in vitro*<sup>1</sup>. But, the processes leading to release of lymphokines by antigen-activated lymphocytes, the mode of action of these lymphokines and their exact role in cell-mediated immunity are still not well defined. It has, however, been recognised that *in vitro* activation of immune lymphocytes by soluble antigens is macrophage dependent and that this activation is under the control of gene products of the major histocompatibility complex (*H-2* in the mouse)<sup>2</sup>. Using a Moloney murine sarcoma virus (MSV)-induced tumour system, we have shown, in agreement with reports of some other systems<sup>3,4</sup>, that immune T lymphocytes required macrophages for migration inhibition factor (MIF) production and, in addition, only histocompatible macrophages could assist immune T lymphocytes for MIF release after stimulation with soluble tumour-associated antigens<sup>5</sup>. We report here that gene products of the *H-2* complex regulated the macrophage-immune lymphocyte interaction for MIF release when soluble tumour extracts were used as the source of antigen. In contrast, when intact tumour cells were used as the source of antigen, a macrophage requirement was not detectable. Moreover, the direct lymphocyte-tumour cell interaction for MIF release was not under *H-2* restriction, since allogeneic as well as syngeneic tumour cells could activate MIF release from immune lymphocytes. These findings suggest the existence of at least two different pathways for MIF production, reflecting perhaps the activation of two distinct subpopulations of T lymphocytes or the activation of T lymphocytes at two different stages of differentiation.

To assess MIF production we used an indirect Agarose droplet assay<sup>6</sup>. Immune spleen cells (ISC) were removed from C57BL/6N (B6) mice 12-14 d after inoculation of a regressor strain of MSV. ISC were depleted of macrophages (d-ISC) by treatment with carbonyl iron powder and magnet<sup>6</sup> or by passage over rayon adherence columns<sup>6</sup> or Sephadex G-10 columns<sup>7</sup>. To generate MIF in the presence of soluble tumour-associated antigens, B6 d-ISC were incubated with normal peritoneal exudate cells (PEC) induced by light mineral oil and treated with anti-Thy-1.2 antisera plus complement. Two sources of soluble tumour-associated antigens were used: a 3 M KCl extract from Rauscher virus-induced ascitic lymphoma (RBL-5) and a 3 M KCl extract from chemically induced ascitic lymphoma [EL4 (G-)]. RBL-5 cells carry the relevant antigens to which B6 ISC are sensitised, whereas EL4 (G-) do not<sup>8</sup>. Alternatively, MIF was produced from B6 d-ISC by incubation with tissue culture RBL-5 cells or cryopreserved RLV or MLV ascitic tumour cells treated with puromycin (20 µg per 10<sup>7</sup> cells). 2-Mercaptoethanol at the final concentration of 5 × 10<sup>-5</sup> M was added to the cultures since it was found to increase the levels of MIF production by d-ISC. Each experiment was performed in quadruplicate and repeated at least 5 or 6 times. In the culture conditions used, NSC plus RBL-5 tissue culture cells or RBL-5 cells alone were found negative for MIF production as shown in a previous report<sup>5</sup>.

Table 1 shows MIF production by ISC in response to 3 M KCl soluble tumour extracts of RBL-5 cells while the ISC, depleted of macrophages, failed to release detectable amounts of MIF when stimulated with soluble tumour antigen. The reaction was antigen-specific because no MIF production was observed with 3 M KCl soluble extracts of EL4 (G-). However, we were able to restore the ability of d-ISC to produce MIF by the addition of syngeneic PEC or PEC from B10 mice sharing the same *H-2* complex, but differing at many other genetic loci from B6 mice. In

contrast, PEC from B10.A and B10.D2 mice which are congenic to B10 mice and differ only at the *H*-2 locus were not able to restore MIF production by B6 d-ISC in response to the antigen. Allogeneic PEC from BALB/c mice were also unable to cooperate with d-ISC in MIF production. Similar results have been observed with BALB/c mice bearing tumours induced by a regressor strain of Moloney murine sarcoma virus (unpublished). In a previous study<sup>3</sup> we showed that the inability of allogeneic macrophages to cooperate in MIF production was not due to a malfunction of macrophages or to an inhibitory effect in allogeneic cell mixtures, so these results indicate that the ability of macrophages to assist d-ISC in the production of MIF in response to a soluble antigen is controlled by gene products mapping in the *H*-2 complex.

Since *in vivo* lymphocytes come in contact with tumour antigens in both soluble form and in insoluble form (as tumour cells), we felt it was important to examine MIF production from immune lymphocytes stimulated with intact tumour cells instead of soluble tumour-associated antigens and to compare the role of macrophages with the two forms of antigen. Table 2 shows that B6 ISC, depleted of macrophages by different techniques, were able to produce MIF when the antigen was on intact tissue culture tumour cells. Moreover, MIF was already detectable at 4 h after initiation of culture while using soluble tumour extracts. MIF production required 14–16 h in addition to the preincubation of the soluble antigen with macrophages. Since the RBL-5 cells used were from an established culture cell line devoid of macrophages and the percentage of macrophages after treatment with carbonyl iron powder plus magnet in association with rayon adherence column was about 0.1%, as evaluated by latex particle ingestion and esterase staining<sup>10</sup>, MIF production in response to intact tumour cells as antigen did not have a detectable requirement for macrophages. As *H*-2 compatibility is required for the interaction between PEC and d-ISC in the induction of MIF by soluble antigen, it was of interest to determine if the same restriction held for the interaction between d-ISC and tumour cells in the generation of MIF. Table 3

**Table 1** Requirement of *H*-2 compatible macrophages for MIF production by B6 ISC in presence of soluble tumour-associated antigens

	Source of PEC	PEC <i>H</i> -2 type	3 M KCl RBL-5	3 M KCl EL4 (G-)
ISC	—	—	0.78*	0.98
d-ISC	—	—	1.07	1.05
"	B6	b	0.73

"	B10.A	a	1.01	
"	B10.D2	d	1.07	
"	BALB/c	d	1.05	

B6 ISC ( $5 \times 10^6$  ml), untreated or treated by rayon adherence columns (d-ISC) and mixed with  $2.5 \times 10^5$  peritoneal exudate cells (PECs) from normal B6, B10, B10.A, B10.D2 and BALB/c mice, were incubated with 3 M KCl extracts of RBL-5 or EL4 (G-) tumour cells. After 4 h at 37 °C the cell mixtures were washed and resuspended in 1 ml of fresh medium containing 0.5% foetal bovine serum (FBS) for 42 h at 37 °C in 5% CO<sub>2</sub> atmosphere. The supernatants, adjusted to 10% FBS, were tested on normal B6 PEC induced by light mineral oil. Two  $\mu$ l droplets of Agarose medium solution, containing  $8 \times 10^5$  PEC, were placed with a microdispenser (Drummond Scientific) in the centre of each well of Falcon plastic Microtest II (3040) culture plates. Each droplet was allowed to solidify at room temperature for 5 min and then 0.1 ml of stimulated or control culture supernatants was added. After 24 h at 37 °C in a humidified 5% CO<sub>2</sub> atmosphere the migration area images were projected, traced and measured by planimetry.

\* Migration index (M.I.) where

$$\text{M.I.} = \frac{\text{Migration area with stimulated supernatant}}{\text{Migration area with unstimulated control supernatant}}$$

All the M.I. under 0.85 were considered positive as determined previously<sup>3</sup>.

**Table 2** MIF production by macrophage-depleted B6 ISC in response to intact tumour cells

Treatment of ISC	Tumour Cells	
	RBL-5	EL4 (G-)

Rayon adherence column	0.64	0.97
Sephadex G-10 column	0.41	1.05
Carbonyl iron-magnet + rayon adherence column	0.52	1.02

B6 ISC ( $5 \times 10^6$ ), depleted of macrophages by various techniques, were mixed with  $5 \times 10^6$  RBL-5 tissue culture cells or EL4 (G-) tumour cells in 1 ml of medium containing 0.5% FBS and incubated for 48 h at 37 °C in 5% CO<sub>2</sub> atmosphere. The supernatants, adjusted to 10% FBS, were treated as described in Table 1.

\* Migration index calculated as in Table 1.

shows that d-ISC were able to produce MIF in response to tumour-associated antigens on allogeneic cells as well as on syngeneic tumour cells. At the ratio of 10:1 effector cells: tumour cell no activity was observed with normal spleen cells in the presence of allogeneic target cells, excluding the possibility of MIF release by allogeneic stimulation as has been observed with longer periods of incubation<sup>11</sup>.

These results demonstrated that tumour-associated antigens stimulate MIF production by immune lymphocytes by two different mechanisms. In the first one, involving soluble tumour-associated antigens, responses occur only when the antigens are presented on macrophages sharing the same *H*-2 of the mice used for *in vivo* sensitisation. In the second one, involving intact target cells, the tumour-associated antigens on the membrane of the tumour cells seem to be sufficient by themselves, independent of *H*-2 products on their surface and of macrophages, to stimulate the immune lymphocytes to produce MIF. The lack of *H*-2 restriction in the mechanism of direct lymphocyte-tumour cell interaction seen in this study is in agreement with other findings from our laboratory indicating that the killing of tumour cells by immune T lymphocytes as measured by 16–18 h <sup>51</sup>Cr assay is not under *H*-2 restriction<sup>12,13</sup>. Plata *et al.* also obtained results showing that *H*-2 restriction in the MSV system is not absolute<sup>14</sup>. The characteristics of the MIF response to soluble tumour antigens are similar to those observed in the induction phase of the immune response in other systems<sup>2</sup>, in which lymphocytes recognise soluble antigens only when bound to the *H*-2 products of the macrophage membrane, and our results are in accord with the 'complex antigenic determinant model' proposed by Thomas and Shevach<sup>15</sup>. On the other hand, the tumour-associated antigens presented on intact tumour cells would seem to allow stimulation of immune lymphocytes directly, without the requirement for macrophages or for similarity at the *H*-2 complex. This might be accounted for by a

**Table 3** Ability of macrophage-depleted B6 ISC to produce MIF in presence of syngeneic as well as allogeneic tumour cells

Tumour cells	<i>H</i> -2 type	Inducing agent	ISC	NSC
RBL-5	b	RLV*	0.76†	0.99

† Migration index calculated as in Table 1.

reaction to cell-bound antigens by a different subpopulation of lymphocytes or by lymphocytes at a different stage of differentiation, perhaps the same subpopulation of cells which are capable of cytotoxicity against intact syngeneic or allogeneic tumour target cells (which also have no macrophage requirement). Alternatively, MIF production by immune lymphocytes to soluble tumour antigens versus intact tumour cells may be in response to different antigenic specificities, only one of which requires the aid of *H-2* compatible macrophages. In any event, the lack of *H-2* restriction in direct lymphocyte-tumour cell interaction has interesting implications for the mechanisms involved with *in vivo* tumour rejection, as it has been shown previously that by immunising with allogeneic BALB/c lymphoma (LSTRA), B6 mice could be protected from challenge with a syngeneic tumour (MBL-2)<sup>16</sup>.

## Correction of human mucopolidosis II enzyme abnormalities in somatic cell hybrids

THE mouse genome has been used to correct the abnormal enzyme phenotype of a human neurodegenerative disorder and to provide information on the nature of the molecular defect. This has been demonstrated in man-mouse somatic cell hybrids using human cells derived from an individual with mucopolidosis II. Mucopolidosis II (ML II) or I-cell disease is a rare fatal childhood storage disease which is associated with deficiencies and electrophoretic abnormalities of several lysosomal hydrolases<sup>1-4</sup>. Somatic cell hybridisation provides a methodology for examining the expression of mutant genes and for identifying and mapping genes associated with human enzyme abnormalities. We have examined the isozyme patterns of six enzymes altered in this disorder in man-mouse hybrids formed with fibroblasts from an ML II patient. These altered enzymes showed corrected patterns of expression in cell hybrids. Since several human enzymes are corrected, a defect in the post-translational processing of lysosomal enzymes is suggested. Previous studies fusing human lysosomal storage disease cells with rodent cell lines have failed to demonstrate correction of the enzyme deficiencies by the rodent genome<sup>5-8</sup>. We present here the first example of the correction of an abnormal enzyme

phenotype associated with a human lysosomal storage disease by fusing human and mouse genomes.

Children affected with the autosomal recessive ML II disorder show Hurler-like clinical features with growth and mental retardation and mucopolysaccharide and glycolipid storage culminating in death by age 2-6 yr (refs 1, 2). Cultured fibroblasts from ML II children show large numbers of cytoplasmic inclusions and deficiencies (2-10% of normal) of the lysosomal hydrolases  $\beta$ -hexosaminidase,  $\beta$ -glucuronidase,  $\beta$ -galactosidase,  $\alpha$ -galactosidase,  $\alpha$ -mannosidase, arylsulphatase, and  $\alpha$ -fucosidase<sup>3,4</sup>. Many of these enzymes are found at elevated levels in culture media and in serum<sup>4,9</sup>. Altered electrophoretic phenotypes have been observed for  $\beta$ -hexosaminidase<sup>10</sup> and several hydrolases excreted from ML II cells<sup>11</sup>. We have reported altered phenotypes for  $\beta$ -hexosaminidase, acid phosphatase<sub>2</sub>,  $\alpha$ -mannosidase, esterase-A<sub>4</sub>, and adenosine deaminase-d in cultured ML II fibroblasts<sup>12</sup>. These abnormalities provide markers for determining if the defect can be corrected by the addition of normal genetic material through cell hybridisation.

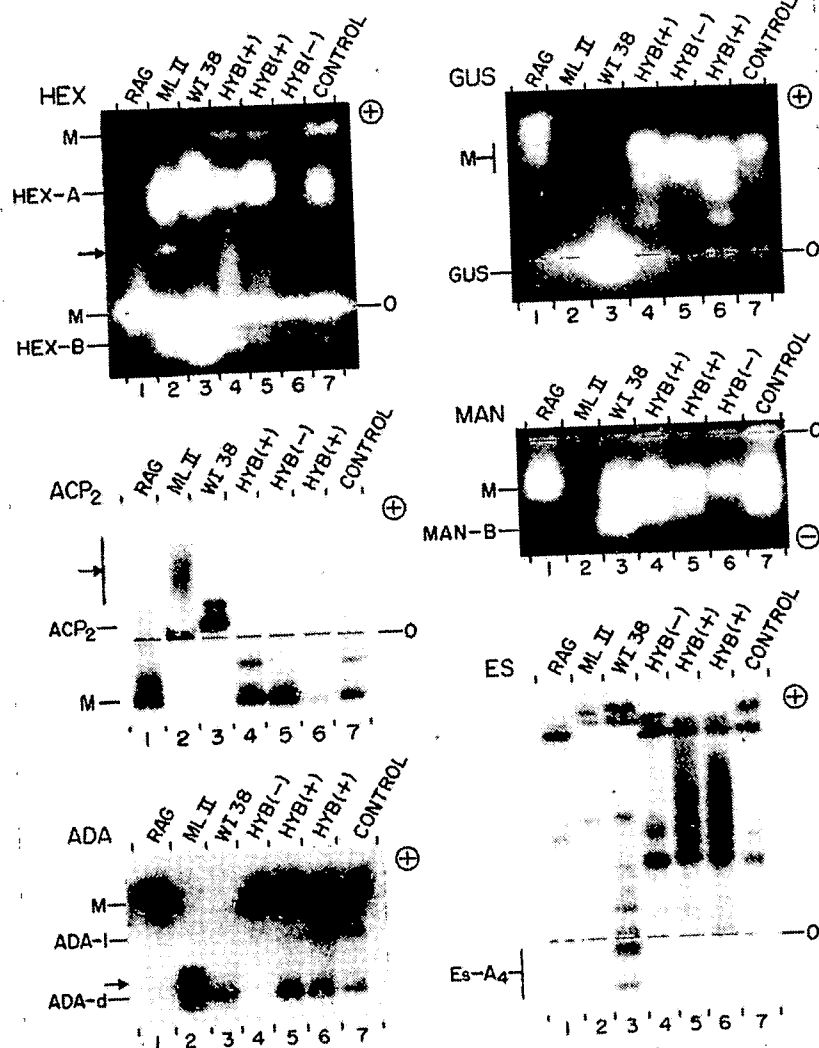

Mucopolidosis II fibroblasts (GM 1006, Human Genetic Mutant Cell Repository) were established from a female patient (L.T.) with ML II symptoms and multiple lysosomal enzyme deficiencies<sup>12,13</sup>. ML II fibroblasts were hybridised with two mouse cell lines: RAG (HPRT<sup>-</sup>) and LM/TK<sup>-</sup>, using Sendai virus as described previously<sup>14,15</sup>. Thirty-six independent clones were isolated consisting of 20 ML II  $\times$  RAG hybrids (ICR) and 16 ML II  $\times$  LM/TK<sup>-</sup> hybrids (ICL). Hybrid clones appeared with a frequency of about 10<sup>-4</sup>. Primary hybrids were selected, cloned, expanded and collected as described previously<sup>14</sup>. Enzyme assays of hybrids were accomplished at early passages<sup>3,4</sup> to maximise the number of human chromosomes retained in hybrids.

Enzymes with altered electrophoretic patterns in ML II fibroblasts were examined after cell hybridisation. Previously it was reported that  $\beta$ -hexosaminidase (HEX), acid phosphatase<sub>2</sub> (ACP<sub>2</sub>), and adenosine deaminase-d (ADA-d) have altered electrophoretic banding patterns in ML II fibroblasts<sup>10,12</sup>. The normal and ML II electrophoretic patterns of HEX, ACP<sub>2</sub>, and ADA-d in human fibroblasts are compared in Fig. 1. Mobility of these enzymes in ML II  $\times$  mouse cell hybrids was examined and compared with control hybrid patterns. Figure 1 shows that in ML II hybrids HEX, ACP<sub>2</sub>, and ADA-d were identical to controls. Thus,  $\beta$ -hexosaminidase showed normal mobility of the human HEX<sub>A</sub> and HEX<sub>B</sub> bands and failed to demonstrate the altered HEX band seen in ML II fibroblasts. Human ACP<sub>2</sub> was identified in hybrids predominantly as the man-mouse ACP<sub>2</sub> intermediate heterodimer and revealed normal electrophoretic mobility and expression. Human ADA-d was also identical to the ADA-d band in control hybrids.

Enzymes severely deficient in ML II fibroblasts were also examined in cell hybrids. Figure 1 demonstrates that the lysosomal enzymes  $\beta$ -glucuronidase ( $\beta$ GUS),  $\alpha$ -mannosidase (MAN<sub>B</sub>), and esterase-A<sub>4</sub> (ESA<sub>4</sub>) from extracts of ML II fibroblasts are weakly detected on starch gels. But human  $\beta$ GUS, MAN<sub>B</sub>, and ESA<sub>4</sub> in ML II  $\times$  mouse cell hybrids showed levels of expression on starch gels similar to control hybrids (Fig. 1). Human chromosomes are eliminated in man-mouse cell hybrids, so not every hybrid clone retained all the lysosomal enzyme markers. But, in each of the 36 hybrid clones examined, at least one of the lysosomal enzymes was retained and demonstrated the normal phenotype. A similar correction pattern was not observed by co-cultivation of mouse and ML II cells or by mixing of cell homogenates. The mouse enzyme pattern was never altered in hybrid clones.

It is possible that the chromosome on which the ML II gene is located is lost in these cell hybrids. Loss of the ML II chromosome might result in the corrected expression of the affected enzymes. Evidence supports complementation of the ML II defect since in 36 independent hybrids normal phenotypes of the enzymes were observed in each hybrid clone. The human chromosome complement in hybrid clones was determined

**Fig. 1** Starch gel electrophoretic patterns of lysosomal enzymes in ML II  $\times$  mouse cell hybrids. Enzymes shown include *N*-acetyl- $\beta$ -hexosaminidase (HEX); acid phosphatase, (ACP<sub>2</sub>); adenosine deaminase (ADA);  $\beta$ -glucuronidase (GUS); lysosomal  $\alpha$ -mannosidase (MAN<sub>B</sub>); and esterase-A<sub>4</sub> (ESA<sub>4</sub>). Channels (1) RAG, mouse parental cell line; (2) ML II cultured fibroblast line GM 1006; (3) normal human fibroblasts, WI-38; (4-6) ML II  $\times$  mouse cell hybrids; (7) control man-mouse hybrids showing normal positive human enzyme expression. Control hybrids were formed with WI-38 or other normal human fibroblasts fused to RAG cells<sup>15</sup>. HYB(+) indicates hybrid clones positive for the human enzyme and HYB(-) indicates negative human enzyme expression. Arrows indicate the altered HEX, ACP<sub>2</sub>, and ADA-d, bands in ML II fibroblasts. The ML II extract for HEX was concentrated to demonstrate the altered HEX band. Differences in mobility of the rodent GUS band in hybrids is due to genetic variation in the mouse parental cells previously reported<sup>21</sup>. Starch gel electrophoretic procedures and enzyme staining were as described previously<sup>12</sup>.

by examining 35 enzyme markers representing each of the human chromosome linkage groups<sup>15,16</sup>. Although individual hybrids did not retain all human chromosomes, the entire genome was represented when all hybrids were taken together. This evidence suggests that the ML II defect was present in hybrids, but was complemented by the mouse genome.

Correction of ML II enzyme defects was also tested by examining linkage relationships of affected enzymes in cell hybrids. The negative expression of a deficient enzyme could result from either the loss of the chromosome encoding the enzyme or deficiency due to the presence of the ML II mutant gene. This was tested by examining segregation patterns of lysosomal enzymes with other enzymes assigned to the same chromosome. Concordant segregation was examined for ESA<sub>4</sub> linked to LDH<sub>A</sub> on chromosome 11 (ref. 14); HEX<sub>A</sub> linked to MPI, PK, and IDH<sub>M</sub> on chromosome 15 (refs 17, 18); and MAN<sub>B</sub> which we have assigned to chromosome 19 with GPI and PEPD (ref. 16). The ESA<sub>4</sub>, HEX<sub>A</sub>, and MAN<sub>B</sub> lysosomal enzymes in hybrids revealed normal segregation patterns with their linked markers (Table 1). Thus when the lysosomal enzyme was absent, other markers on the same chromosome were also absent. These normal segregation patterns of affected enzymes and their linked markers suggest further the correction of the ML II enzyme phenotype.

Cell hybridisation studies with other human lysosomal storage disorders have not demonstrated correction of the deficient lysosomal enzymes. Thus in Tay Sachs-rodent hybrids, the deficient human HEX<sub>A</sub> enzyme is not demonstrated<sup>5</sup>. Sandhoff-rodent hybrids do not express the deficient human HEX<sub>A</sub> and HEX<sub>B</sub> bands<sup>6,8</sup>. Fabry-hamster cell hybrids fail to express

detectable human  $\alpha$ -galactosidase<sup>7</sup>, and hybrids with mannosidosis fibroblasts do not express human lysosomal MAN<sub>B</sub> (ref. 8).

There is evidence to suggest that ML II may be associated with a deficiency in the metabolism of sialic acid coupled glycoproteins. Several lysosomal enzymes from ML II cells including HEX, ACP<sub>2</sub>, and MAN<sub>B</sub> seem to be excessively sialylated<sup>11,12</sup>. Cultured ML II fibroblasts have been reported to contain high levels of sialic acid<sup>19</sup> and are severely deficient for an acid sialidase<sup>19,20</sup>. It is not known if this sialidase deficiency represents the primary ML II lesion, however.

Complementation of ML II enzyme defects in man-mouse hybrids is indicated since (1) the enzymes HEX, ACP<sub>2</sub>, and ADA-d had normal electrophoretic patterns in ML II hybrids;

**Table 1** Segregation of lysosomal enzymes with linked enzyme markers in ML II  $\times$  mouse hybrids

	+/+	+/-	-/+	-/-
ESA <sub>4</sub> /LDH <sub>A</sub>	24	0	3	9
HEX <sub>A</sub> /MPI, PK, IDH <sub>M</sub>	20	1	0	15
MAN <sub>B</sub> /GPI, PEPD	26	1	1	8

Human gene assignments of lysosomal enzymes determined from man-rodent somatic cell hybrid studies were reported previously<sup>14-18</sup>. Values are numbers of independent hybrid clones scored positive (+) or negative (-) for expression of enzyme markers. The few discordant clones observed were similar to numbers in control hybrids and are accountable due to different sensitivities of enzyme stains and/or chromosome breakage. Enzyme markers for each hybrid clone were determined from the same cell homogenate.

(2) BGUS, MAN<sub>B</sub>, and ESA<sub>4</sub> showed normal levels of expression; (3) the ESA<sub>4</sub>, HEX<sub>A</sub>, and MAN<sub>B</sub> enzymes showed normal linkage relationships; and (4) all the human chromosomes were represented when all hybrids were considered. This evidence suggests that the ML II mutation was present and that the mouse genome can correct the multiple enzyme abnormalities of the ML II disorder.

Correction of enzyme defects in ML II hybrids shows that these enzyme abnormalities are not defects in the primary structure of individual enzymes. Rather, these results are consistent with this disorder resulting from a defect in the post-translational processing of multiple lysosomal enzymes which can be corrected by the mouse genome in man-mouse hybrids.

## Calcium ion regulates chemotactic behaviour in bacteria

CHEMOTAXIS is the process by which bacteria travel to higher concentrations of attractant or lower concentrations of repellent. Its study has attracted wide interest as an example of the stimulus-response network since bacteria are the most primitive of living creatures. Behaviour in peritrichous bacteria is indeed simple: bacteria alternately swim smoothly and tumble, which results in random reorientation for the next swim<sup>1</sup>. Chemotaxis occurs by the increasing tendency of bacteria to tumble when headed in the 'unfavourable' direction and by increasing inclination to swim when the bacteria are headed in the 'favourable' direction (such as towards higher attractant concentrations)<sup>1,2</sup>. Tumbling is caused by clockwise rotation of flagella and swimming by counter-clockwise rotation<sup>3</sup>. Addition of repellent to bacteria causes tumbling; addition of attractant causes swimming<sup>4–6</sup>. Understanding how the switch that controls direction of flagellar rotation is controlled and how the controlling parameter is regulated by changes in attractant or

repellent concentration is necessary to understand chemotaxis. Here I present evidence that for *Bacillus subtilis* the free concentration of internal Ca<sup>2+</sup> ion controls direction of flagellar rotation (high concentrations bringing about tumbling; low concentrations, swimming) and that repellents, which cause tumbling when added to bacteria, work by increasing the flow of Ca<sup>2+</sup> ion across the plasma membrane.

*B. subtilis* was grown in minimal medium, filtered, washed and suspended at about  $1.7 \times 10^7$  bacteria per ml. A23187, an antibiotic that transports divalent cations across membranes and hence tends to equilibrate the free concentrations of these cations in aqueous compartments separated by membranes<sup>7</sup>, was sometimes added as a 1:1000 dilution from a stock in ethanol: 0.1% ethanol itself did not affect behaviour. Samples of 4 or 9  $\mu$ l were then placed, sometimes in a blind experiment, on a washed microscope slide and the bacterial behaviour observed at the top of the drop.

The purpose of the experiment was to regulate the internal concentration of Ca<sup>2+</sup> ion, which is present in very low concentrations because it is normally extruded from bacteria<sup>8</sup>, to see whether the ion might play a role in controlling behaviour. Buffered Ca was added to a basic buffer (Table 1). By adding high concentrations of the chelating agent, EGTA, and CaCl<sub>2</sub> in the correct concentrations, one could stably maintain low concentrations of free Ca<sup>2+</sup> ion. To minimise depletion of cellular Mg, EGTA was chosen because of its low stability constant for Mg<sup>2+</sup> ion ( $10^{1.9}$ ) (ref. 9).

In absence of A23187 in  $10^{-4}$ M Ca<sup>2+</sup> ion, the bacteria swam erratically<sup>10</sup>. As the concentration of free Ca<sup>2+</sup> ion was lowered, the bacteria swam progressively more smoothly. In absence of Ca<sup>2+</sup> ion, they only tumbled occasionally<sup>10</sup>. In fact, it was possible in blind experiments to distinguish, although sometimes with difficulty, the decrease in tumbling between  $10^{-4}$ M and  $10^{-5}$ M,  $10^{-5}$ M and  $10^{-6}$ M,  $10^{-6}$ M and  $10^{-7}$ M,  $10^{-7}$ M and  $10^{-8}$ M, and  $10^{-8}$ M and none.

In presence of A23187, behaviour was dramatically altered. Bacteria became incessant tumblers at  $10^{-7}$ M and higher Ca<sup>2+</sup> ion and, as without A23187, nearly incessant swimmers at  $10^{-8}$ M and lower Ca<sup>2+</sup> ion (Table 1; and see ref. 10). Furthermore, strong attractant,  $10^{-3}$ M alanine,  $10^6$ -fold above its threshold<sup>11</sup>, did not cause swimming in bacteria in  $10^{-7}$ M Ca<sup>2+</sup> ion and A23187. Finally, with no A23187, strong repellent,  $3.2 \times 10^{-6}$ M pentachlorophenol, 32-fold above its threshold<sup>6</sup> did not cause tumbling if the external Ca<sup>2+</sup> ion was  $10^{-8}$ M or lower.

These results indicate that internal Ca<sup>2+</sup> ion is likely to regulate the direction of flagellar rotation. Ca<sup>2+</sup> ion is presumed to bind, with  $K_d$  of  $10^{-7}$  to  $10^{-8}$ M, to the switch that controls

Table 1 Effect of regulation of cytoplasmic Ca<sup>2+</sup> ion using an ionophore and Ca buffer

[Ca <sup>2+</sup> ] <sub>free</sub>	[EGTA] <sub>total</sub>	[Ca <sup>2+</sup> ] <sub>total</sub>	Behaviour in A23187
$10^{-4}$	$10^{-4}$	$2 \times 10^{-4}$	Tumble
$10^{-5}$	$10^{-3}$	$9.94 \times 10^{-4}$	Tumble
$10^{-6}$	$10^{-3}$	$8.63 \times 10^{-4}$	Tumble
$10^{-7}$	$10^{-3}$	$6.13 \times 10^{-4}$	Tumble
$10^{-8}$	$10^{-3}$	$5.935 \times 10^{-4}$	Swim
0	$10^{-3}$	0	Swim

Suspension buffer contained the following components:  $5 \times 10^{-3}$ M piperazine-N, N'-bis(2-ethane sulphonate) pH 6.9,  $3 \times 10^{-2}$ M KCl, 5 mM sodium lactate, 0.05% glycerol,  $3 \times 10^{-4}$ M chelex-100 treated (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub>, and EGTA CaCl<sub>2</sub> as above. A23187 was used at  $1.37 \times 10^{-6}$ M. The concentration of free Ca<sup>2+</sup> ion was calculated from the equation<sup>21</sup>  $[EGTA]_{total} = ([Ca]_t/K[Ca^{2+}]_{free}) - 1/K + [Ca]_{total} - [Ca^{2+}]_{free}$ , using an apparent stability constant ( $K$ ) for Ca-EGTA of  $10^{6.8}$  (ref. 9). Bacteria were grown in minimal medium containing  $10^{-2}$ M Na lactate and 0.1% glycerol to 75 Klett units (filter 66), about  $2.6 \times 10^8$  bacteria per ml. Experiments were carried out as described in ref. 10 except that observation was made at the top of the drop, not near the slide, since bacteria tended to stick to the glass.

direction of flagellar rotation. When the switch is bound with  $\text{Ca}^{2+}$  ion, tumbling (clockwise rotation) is favoured; when unbound, swimming is favoured. Normally the bacteria successfully keep it out since even  $10^{-4}\text{M}$  external  $\text{Ca}^{2+}$  ion the bacteria do not tumble incessantly. But A23187 readily conveys it into the cell since even  $10^{-7}\text{M}$   $\text{Ca}^{2+}$  ion makes the bacteria perpetual tumblers. Repellent is assumed to bring about a transient depolarisation of the membrane<sup>5,6</sup> and to increase its permeability to  $\text{Ca}^{2+}$  ion since, in absence of A23187, no tumbling response ensues if the external  $\text{Ca}^{2+}$  ion concentration is low enough (see above).

Similar results were obtained in a previous study<sup>10</sup> when EGTA was added to *B. subtilis* in A23187. But, when Mg as well as Ca was removed from cells using A23187 and EDTA, then incessant tumbling ensued. One explanation<sup>12</sup> is that  $\text{Mg}^{2+}$  ion and  $\text{Ca}^{2+}$  ion are antagonists at the switch. Because internal Mg content is very high ( $20\text{--}40\text{ mM}$ )<sup>13</sup>, the fractional change in the concentration of  $\text{Mg}^{2+}$  that occurs during chemotactic stimulation is probably very small; in the absence of  $\text{Ca}^{2+}$ ,  $\text{Mg}^{2+}$  binds to the switch and the cells swim smoothly. In absence of either ion, the switch stays in the tumbling (clockwise) rotation mode.

There is strong evidence that  $\text{Ca}^{2+}$  ion has a universal role in the control of biological processes. It regulates direction of swimming by *Paramecium*, for instance, when *Paramecium* strikes a barrier, the membrane depolarises and  $\text{Ca}^{2+}$  ion enters and causes a change in the direction that the cilia point. Thus, *Paramecium* backs up<sup>14–16</sup>. (This mechanism is similar to the way repellents of *B. subtilis* act; attractants act differently<sup>12</sup>.) When light strikes rhodopsin,  $\text{Ca}^{2+}$  ion flows out of the discs in which rhodopsin is housed into the cytoplasm and there brings about depolarisation of the plasma membrane to begin transmission of the nerve impulse to the brain<sup>17</sup>. Arrival of a nerve impulse to muscle leads to release of  $\text{Ca}^{2+}$  ion from sarcoplasmic reticulum to bring about muscle contraction and its return allows muscle relaxation<sup>18</sup>. Intracellular  $\text{Ca}^{2+}$  ion, which is affected by extracellular  $\text{Ca}^{2+}$  ion, regulates insulin release from the islets<sup>19</sup>. Variations in intracellular  $\text{Ca}^{2+}$  ion, whose fluxes across the plasma membrane of liver are affected by  $\alpha$ -adrenergic hormones, regulate phosphorylase and glucose release<sup>20</sup>. This process is repeated again and again. This special regulatory role for  $\text{Ca}^{2+}$  ion may have been chosen early in evolution; it seems to be the controlling element in the most primitive of sensory systems, chemotaxis in bacteria.

## Histamine induces release of an eosinophil immobilising factor from mononuclear cells

LIBERATION of factors chemotactic for eosinophil granulocytes is often associated with the release of histamine from mast cells and basophils. This is true for the eosinophil chemotactic factor of anaphylaxis (ECF-A), which is secreted together with histamine from mast cells and basophils<sup>1</sup>. It also applies to the generation of chemotactic factors by the activation of complement (C), which leads to the liberation of anaphylatoxin<sup>2</sup>. Therefore, it was of interest to study whether histamine had any effect on the migration of eosinophils towards chemotactic attractants. We describe here a factor which inhibits the migration of eosinophil granulocytes and which is released from mononuclear cells upon incubation with histamine.

Eosinophils were induced in guinea pigs by intraperitoneal injections of a crude extract of *Ascaris suis*, 4 mg twice weekly for at least 2 weeks. Four days after the last injection the cells were collected by peritoneal lavage. The cell suspension contained between 30 and 70% eosinophils, remainder being almost exclusively mononuclear cells. Two cell types could be separated by centrifugal elutriation with a Beckman elutriator rotor<sup>3</sup> to yield an eosinophil rich fraction of 90–97% purity, and an eosinophil poor fraction of mononuclear cells with 1–2% eosinophils.

The eosinophils showed a good chemotactic response to normal human serum which had been treated with baker's yeast (50 mg per ml serum) for 1 h at 37 °C to activate complement (C-activated NHS). They were also attracted to casein at concentrations of 0.5–2.0 mg ml<sup>-1</sup> and, to a lesser extent, to histamine, which exhibited an optimal cell response at a concentration of 10<sup>-5</sup> mol l<sup>-1</sup> (Fig. 1). To

Fig. 1 The effect of histamine at various concentrations on the migration of guinea pig eosinophils of 40% purity towards C-activated NHS. The upper compartment of the chemotaxis chamber contained  $3 \times 10^6$  cells per ml Hank's balanced salt solution (HBSS), to the lower compartment was added per ml HBSS either 50  $\mu$ l of C-activated NHS (dashed line), or histamine (■) or 50  $\mu$ l C-activated NHS plus histamine (●). Chemotaxis was assayed in a modified Boyden chamber using micropore filters of 8  $\mu$ m pore size (Schleicher & Schüll, Göttingen, Germany). The leading front of migration into the filter was measured<sup>15</sup>.

analyse the influence of histamine on the chemotactic migration towards C-activated NHS, histamine at various concentrations was added to the attractant in the lower compartment of a chemotaxis chamber. When the cell preparation contained less than 50% eosinophils, two effects were observed (Fig. 1). Concentrations of  $10^{-4}$  to  $10^{-5}$  mol l $^{-1}$ , which themselves induced chemotactic migration, increased the distance migrated by the eosinophils. At lower concentrations, however, histamine caused a dose dependent inhibition of eosinophil migration, which was most pronounced at  $10^{-8}$  mol l $^{-1}$ . In contrast, when 90% pure eosinophils were employed in the assay, only the enhancing effect at high concentrations but no inhibition of migration at low concentrations was discernable (Fig. 2). This finding suggested that histamine did not inhibit the eosinophils directly, but induced the release of an immobilising factor from cells other than eosinophils. To test this possibility further the mononuclear fraction of peritoneal cells devoid of eosinophils was incubated with and without histamine at  $10^{-8}$  mol l $^{-1}$  for 1 h at 37 °C. The cells were then centrifuged, and eosinophils of 90% purity were suspended in the supernatant and assayed for chemotactic migration towards C-activated NHS. As depicted in Fig. 3, there was some inhibition of eosinophil migration by the 1 h supernatant of mononuclear cells incubated without histamine. However, a marked inhibition of migration by 80% was found when histamine was present during the incubation. The immobilising effect could not be attributed to histamine, since histamine at  $10^{-8}$  mol l $^{-1}$  did not reduce the mobility of pure eosinophils and at higher concentrations was weakly chemotactic itself (Fig. 2).

Furthermore, the histamine antagonists diphenhydramine and metiamide (Smith, Kline and French), although capable of blocking the histamine induced release of the immobilising factor from mononuclear cells, did not affect the inhibition of eosinophil migration when added together with the mononuclear cell supernatant. The immobilising factor was not cytotoxic for eosinophils: at the end of the 2-h incubation period of eosinophils with the mononuclear cell supernatant more than 97% of the cells were found to be viable as tested by trypan blue exclusion. The effect could not be explained by the release of a chemotactic factor

Fig. 2 The effect of histamine at various concentrations on the migration of more than 90% pure eosinophils towards C-activated NHS. C-activated NHS 50  $\mu$ l per ml HBSS (dashed line), histamine only (■), C-activated NHS plus histamine (●).

Fig. 3 The migration of 90% pure eosinophils suspended in HBSS a, the supernatant of the mononuclear cell fraction incubated for 1 h at 37 °C in the absence b and in the presence c of  $10^{-8}$  mol l $^{-1}$  histamine. The columns represent individual data from a representative experiment.

from the mononuclear cells upon histamine treatment, since the supernatant when added alone to the lower compartment of a Boyden chamber did not exhibit chemotactic activity.

We conclude therefore that histamine at a concentration around  $10^{-8}$  mol l $^{-1}$  stimulated mononuclear cells to release a factor which immobilised eosinophils. From a column of Sephadex G-10 the activity was eluted with the total volume indicating that its molecular weight was below 1,000. This precludes its identity with the neutrophil immobilising factor<sup>4,5</sup>, which has a molecular weight of 5,000. Preliminary results indicate that the eosinophil immobilising activity is released from the nonadherent fraction of mononuclear cells and that it affects the eosinophils and not the chemotactic factor.

Various effects of histamine on the function of cells have been described. Aside from an inhibitory effect on the secretory function of mast cells and basophils<sup>6,7</sup> it inhibited the destruction of target cells by cytotoxic T lymphocytes<sup>8</sup>, it reduced the number of plaque forming cells in an *in vitro* primary<sup>9</sup> and secondary<sup>10</sup> immune response, and it suppressed the production of the migration inhibitory factor MIF from immune lymphocytes<sup>11</sup>. What is unusual about the effect of histamine described here is the stimulatory action on the secretory function of mononuclear cells and the low histamine concentration at which this effect is observed.

It has been disputed whether histamine itself is chemotactic for eosinophil granulocytes. Like others<sup>12</sup> we were able to induce increased migration of eosinophils towards a concentration gradient of histamine, but this differed only slightly from the increased random mobility and was considerably less pronounced than the attraction by C-activated NHS, casein or ECF-A. It has been suggested that the chemotactic activity of histamine towards eosinophils was an *in vitro* phenomenon which could not be observed *in vivo*<sup>13</sup>. Others, being unable to detect any chemotactic attraction, nevertheless, observed immobilisation of eosinophils at the site of an injection of histamine<sup>14</sup>. It is conceivable that this effect was induced by the inhibitor of eosinophil migration described here. We suggest that the accumulation of eosinophils observed in certain allergic diseases and in nematode infections may be the result of chemotactic attraction and inhibitor-induced trapping. Furthermore, it seems possible that the inhibitory functions of histamine described by others<sup>8-11</sup> are as well mediated by

inhibitors released from mononuclear leukocytes under the influence of histamine.

## Dark noise in retinal bipolar cells and stability of rhodopsin in rods

FOR the dark-adapted human observer, the absolute visual threshold has been estimated to be the effective absorption of 5–10 photons in an area covered by some 500 rods<sup>1</sup>. Although the quantum statistics of light enter as a factor which determines the frequency of seeing weak light stimuli<sup>1,2</sup>, it has been suggested that there is 'noise' in the visual system which ultimately limits the sensitivity of the eye<sup>3,4</sup>. Each rod in the human eye contains about  $10^8$  rhodopsin molecules, and if the 'noise' arises from events in the rod indistinguishable from the effects of light, there must be an extremely low probability of

spontaneous change produced in any single rhodopsin molecule (or at sites within the rod disk membrane leading to an elementary voltage change in the rod). We have analysed voltage fluctuations in bipolar cells as a probe of rod activity in the dogfish retina. A component of the noise has been identified as photon noise, superimposed on dark noise arising from photon-like events. This part of the dark noise has a large temperature dependence ( $Q_{10}$  about 8), suggesting thermal isomerisation of rhodopsin. The rate constant, extrapolated to 37 °C, would correspond to one isomerisation in 30 s in a human rod, similar to estimates from the absolute threshold for human vision.

Using intracellular microelectrodes, we have obtained recordings from bipolar cells in the dark-adapted retina of the dogfish, *Scyliorhinus canicula*. This retina contains primarily rod photoreceptors. The bipolar cells, which depolarise with light<sup>5,6</sup>, have a high flash sensitivity indicative of a large dynamic voltage gain at the rod-bipolar synapse<sup>6</sup>. Voltage fluctuations in the bipolar cells in darkness and during steady light were analysed for their power spectral distribution.

As shown in Fig. 1, the voltage noise increased from its dark level after presentation of light in the range  $2 \times 10^{-3}$  to 1 photon  $s^{-1} \mu m^{-2}$ . The power spectrum of the noise in complete darkness and during dim steady light consists of two components, one with a half-power point near 1.3 Hz and the other near 7 Hz (Fig. 2). Several features of the cell's response to light suggest that the low-frequency component of the noise arises from fluctuations in the rate of photons absorbed by the bipolar cell's rod pool ('photon noise'), superimposed on a noise present in the dark. The spectrum of the response to a dim, brief flash of light had power distributed over a similar range of frequencies as the low-frequency component of the noise spectrum (Fig. 2). At low light levels (less than 0.02 photon  $\mu m^{-2} s^{-1}$ ), the mean depolarisation produced by steady light is proportional to the light intensity. The contribution to the total noise variance, obtained from the area under the low frequency component, increases linearly with light intensity at low light levels, as expected if the underlying statistics of the source are Poisson. It was further found that the peak amplitude of the elementary event underlying the low frequency component during steady dim light was the same as that obtained from an analysis of the fluctua-

Fig. 1 Voltage fluctuations in a dogfish bipolar cell in darkness and during steady full-field illumination by blue-green light. Mean light flux density at 495 nm (photons  $s^{-1} \mu m^{-2}$ ): a, dark; b,  $1.9 \times 10^{-3}$ ; c,  $7.4 \times 10^{-3}$ ; d,  $2.1 \times 10^{-2}$ ; e, 0.92; f, 8.5. (See ref. 6 for methods of voltage recording and light calibration.) Membrane potential in the dark -47 mV; total noise variance 0.0310 mV<sup>2</sup> (corrected for electrode noise observed outside the cell). Mean depolarisation and noise variance during steady light were for each intensity illustrated (in order of increasing intensity) 0.34 mV, 0.103 mV<sup>2</sup>; 1.1 mV, 0.163 mV<sup>2</sup>; 1.8 mV, 0.227 mV<sup>2</sup>; 7.2 mV, 0.101 mV<sup>2</sup>; 9.5 mV, 0.0196 mV<sup>2</sup>. The highest intensity illustrated produced saturation of the voltage response. Peak depolarisation of the cell in response to a flash of light was 30 mV. Note that the noise variance reached a maximum value and then fell as light intensity increased. Temperature 17 °C.

Fig. 2 Power spectra of voltage noise in darkness (○) and during steady dim light (●), compared with the spectrum of the response to a dim flash (△, the modulus squared of the Fourier transform of the flash response). Analogue data, recorded on an FM tape recorder, were filtered by a low pass filter with a cut-off frequency of 100 Hz, and sampled at 256 Hz. Spectra, weighted by a Hanning function, were computed from data blocks containing 1,024 points using the fast Fourier transform. The spectra shown are the averages obtained from 32–76 s of record and have been corrected for the electrode noise (mainly  $1/f$  noise). The spectrum of the response to a flash of light represents the average spectrum of 12 responses to 15-ms flashes delivering  $0.01 \text{ photons } \mu\text{m}^{-2}$ , which gave a mean response of 2.3 mV. The spectrum of the dark noise has been subtracted and the result arbitrarily scaled to the lowest frequency points for the spectrum in dim steady light ( $4 \times 10^{-3} \text{ photons s}^{-1} \mu\text{m}^{-2}$ , mean depolarisation 0.33 mV). Noise variance in the dark attributable to 'photon-like' events =  $0.032 \text{ mV}^2$ . Noise variance in dim steady light attributable to 'photon noise' + 'photon-like' events  $0.082 \text{ mV}^2$ . Membrane potential in the dark  $-54 \text{ mV}$ ; maximum peak depolarisation with bright light 23 mV; temperature  $23^\circ \text{C}$ .

tions in response to brief flashes of dim light<sup>7</sup>. This provides strong evidence that the same Poisson process is involved. The estimated peak amplitude of the response produced in the bipolar cell by one photon absorbed within its rod pool has an average value of 0.25 mV.

The response of photoreceptors to flashes of dim light can be described by equations of the same form as the impulse response of an electrical network consisting of a chain of low pass filters<sup>8,9</sup>. It is assumed that the narrow band character of the low frequency component of bipolar cell noise arises from the properties of the rod response rather than the filter characteristics of the rod-bipolar synapse. In that case, the low frequency component of the dark noise could arise from events in the rod indistinguishable from the effects of light. The 'dark light', which would be the photon equivalent for the low frequency component of the dark noise, can be obtained from the intercept on the light intensity axis in a plot of variance against light intensity. For the cell illustrated in Fig. 2, the 'dark light' would be equivalent to a photon flux density of  $2 \times 10^{-3} \text{ photon } \mu\text{m}^{-2} \text{ s}^{-1}$ . This would correspond to an event equivalent to one photoisomerisation in a rod every 160 s, if the effective collecting area for a dogfish rod is  $3 \mu\text{m}^2$  (ref. 6).

The 'dark light' was found to be strongly temperature dependent. An activation energy of  $36 \text{ kcal mol}^{-1}$  was

calculated from an Arrhenius plot (Fig. 3) of the mean rate of spontaneous events per rod as a function of absolute temperature, giving a  $Q_{10}$  of 7.8 at a temperature of  $20\text{--}30^\circ \text{C}$ . The activation energy associated with the dark light is significantly higher than for the processes governing the kinetics of the response of photoreceptors to flashes of light;  $10 \text{ kcal mol}^{-1}$  ( $Q_{10} = 1.8$ ) for turtle cones<sup>8</sup> and  $16 \text{ kcal mol}^{-1}$  ( $Q_{10} = 3$ ) for rat rods<sup>9</sup>. This would make it unlikely that such processes occur spontaneously at the requisite rate. If the dark light arose from spontaneous changes in rhodopsin molecules, these changes might be of two kinds, thermal denaturation or thermal isomerisation. The products of the former are denatured opsin and 11-*cis*-retinal<sup>10</sup>, whereas for the latter they are opsin and *trans*-retinal, as in photoexcitation<sup>11</sup>. The rate constant at  $20^\circ \text{C}$  would be  $1.2 \times 10^{-11} \text{ s}^{-1}$ , based on Fig. 3 and an estimate of  $3 \times 10^8$  rhodopsin molecules per dogfish rod. Applying absolute reaction rate theory<sup>12</sup>, we find that the Gibbs free energy of activation  $\Delta G^\ddagger$  for the process underlying the dark light is  $32 \text{ kcal mol}^{-1}$ , and the entropy of activation  $\Delta S^\ddagger$  is  $13 \text{ cal mol}^{-1} \text{ degree}^{-1}$ . The entropy of activation is very much less than for thermal denaturation of rhodopsin<sup>10</sup>. We conclude, therefore, that denaturation occurs at a comparatively insignificant rate in the eye over the temperature range of  $15\text{--}25^\circ \text{C}$  and/or it does not give rise to responses in rods which resemble photoreponses.

The activation energy of  $36 \text{ kcal mol}^{-1}$ , determined from the dark noise, lies between the value of  $26 \text{ kcal mol}^{-1}$  for thermal *cis-trans* isomerisation of the chromophore, retinal, in a non-polar solvent, as determined by Hubbard<sup>13</sup>, and an estimate of about  $48 \text{ kcal mol}^{-1}$  for the activation energy for thermal isomerisation of rhodopsin<sup>14,15</sup>. The estimate of  $48 \text{ kcal mol}^{-1}$  for rhodopsin is not based on direct measurement but derives from the assumption that there is a fixed minimum energy required for absorption of

Fig. 3 Arrhenius plot of the dark rate of spontaneous events in a dogfish rod, equivalent to photoisomerisation, against the reciprocal of the absolute temperature. The ordinate is the log of the mean rate of effective photon absorption by rods which would be required in order to give 'photon' noise variance in the bipolar cell equal to the variance in the dark associated with the low frequency component of the noise (see text). An effective collecting area of  $3 \mu\text{m}^2$  for a rod in the tapetal region of the retina has been assumed<sup>6</sup>. The slope of the line corresponds to an Arrhenius activation energy of  $36 \text{ kcal mol}^{-1}$ .

a photon<sup>15-18</sup>, which would correspond to the thermal activation energy for isomerisation. This would, however, predict a very much larger energy of activation for *cis-trans* isomerisation of retinal than was observed by Hubbard<sup>21</sup> (see also ref. 18). We conclude tentatively that the present results are consistent with thermal isomerisation of rhodopsin. Extrapolation to 37 °C would give a rate constant of  $3.5 \times 10^{-10} \text{ s}^{-1}$ . Denton and Pirenne<sup>3</sup>, and Barlow<sup>4</sup>, have concluded that in the human the rate constant for thermal isomerisation of rhodopsin must be less than  $10^{-9} \text{ s}^{-1}$  in order to account for the reliability of detection at absolute threshold. The low rate of spontaneous isomerisation of rhodopsin is one of the features of the visual system underlying the ability to detect the absorption of a few photons.

It is not yet clear whether the second component of the noise in bipolar cells reflects synaptic noise arising from fluctuations in the release of transmitter at the rod-bipolar synapse<sup>19</sup> or noise generated more distally in the photoreceptor, possibly from interaction of an intracellular transmitter with the surface membrane of the rod<sup>20-22</sup>.

## Acetylcholine receptor conformational transition on excitation masks disulphide bonds against reduction

KARLIN and Bartels<sup>1</sup> found that dithiothreitol (DTT) inhibits the responses induced by acetylcholine (ACh) in the *Electrophorus electricus* electroplex preparation and that 5,5'-dithio-bis-(2-nitrobenzoic acid) completely restored the membrane sensitivity to ACh. These results illustrate the importance of disulphide bonds for acetylcholine receptor (AChR) function, and work on other preparations with nicotinic AChRs gave similar results<sup>2-9</sup>. Several facts suggest that DTT affects AChRs specifically; (1), the significance of the quaternary ammonium group in the molecules of alkylating and acylating agents for the rate of their reaction with the AChR reduced by DTT<sup>10</sup>; (2) changes in pharmacological specificity seen in the modified receptor<sup>5,7,10</sup>; (3) the decrease in the slope of the dose-response curve to carbamylcholine expressed as the Hill plot<sup>11</sup>; and (4) the increase in *d*-tubocurarine affinity to the AChR active site<sup>5</sup>. If we could protect the receptor against chemical modification by an agonist or antagonist, this would be

Fig. 1 The effect of disulphide bond reduction by DTT and reoxidation by DTBCh on soma membrane of *Limnaea stagnalis* neurone. 1, Control; 2, after 14 min treatment with DTT  $1 \times 10^{-3} \text{ M}$ ; 3, after 15 min reoxidation by DTBCh  $1 \times 10^{-4} \text{ M}$ . *a*, The time course of membrane conductance change induced by ACh  $2 \times 10^{-6} \text{ M}$ . The times of ACh and Ringer solution (R) addition are marked by arrows. *b*, Voltage-current plots of the neurone response to ACh  $2 \times 10^{-6} \text{ M}$ . The reversal potential,  $E_r$  (obtained by extrapolation), does not change after the neurone exposure to DTT. *c*, The steady-state voltage-current curves of electroexcitable membrane. In (*a*) and (*b*) membrane potential was held at the resting potential (RP) level and a three-level voltage sequence (RP + 10 mV, RP, RP - 10 mV) was applied. ChRM conductance values were calculated according to current changes produced by membrane potential shifts in equal periods of time (dots in (*a*) and in Figs. 2 and 3). Curves were drawn by hand. In (*c*) membrane potential was held at RP level and a serial depolarising and hyperpolarising voltage steps (10 mV) were applied. Impulse duration, 5 s. Potassium outward currents were measured at the end of the steps.

the most reliable proof of the specificity of modifying agent action<sup>12</sup>. We present here a detailed study of the action of DTT on nicotinic AChRs of completely isolated *Limnaea stagnalis* neurones in order to clarify the ability of various cholinergic ligands to protect the receptor disulphide bonds against reduction by DTT.

Identified giant neurones from the right and left parietal ganglia of molluscs were isolated by treating brain preparations with trypsin and then Pronase, and separated mechanically with tungsten microneedles and glass micropipettes<sup>13,14</sup>. Nerve cells were placed into the chamber (effective perfusion volume 0.2 ml, rate of perfusion 15-20 ml per min) and continuously perfused with *Limnaea* Ringer solution containing NaCl 100 mM, KCl 1.6 mM, CaCl<sub>2</sub> 4 mM, MgCl<sub>2</sub> 1.5 mM, Tris-hydroxymethylaminomethane 0.12 g l<sup>-1</sup>, and HCl to pH 7.5. All the drugs were dissolved in this medium and applied to the neurone membrane by passing constant-flowing (gravity feed) solution. Each neurone was impaled with two microelectrodes (2.5 M KCl filled). The perfusing medium was connected with the virtual ground of an operational amplifier through the agar bridge. Drug action was estimated using the voltage-clamp technique according to the membrane conductance change at the resting potential level.

Application of DDT  $1 \times 10^{-4}$ - $1 \times 10^{-3} \text{ M}$  for 2-15 min markedly depressed responses to a standard ACh concentration (Fig. 1*a*), while the reversal potential of ACh-responses and the steady-state current-voltage curve of electroexcitable membrane did not change (Fig. 1*b* and *c*, respectively). The sensitivity of neurone membrane to ACh was restored after treatment with dithiobischole<sup>19</sup> (DTBCh) which is known to oxidate thiol groups (Fig. 1*a*, *b*).

The reversible inhibition of cholinergic membrane

**Fig. 2** Protection of ChRM against the DTT effect by a high ACh concentration. 1 And 3, response of the neurone to ACh  $2 \times 10^{-6}$  M before and after exposure to DTT  $1 \times 10^{-3}$  M for 2 min in the presence of ACh  $5 \times 10^{-5}$  M. 2, Response to conditioning ACh concentration; the duration of pretreatment with ACh was about 2 min.

(ChRM) by DTT could be converted into irreversible inhibition by application of an SH-specific alkylating agent (such as *N*-ethylmaleimide (NEM), any quaternary ammonium *N*-alkyl derivative of maleimide, or bromoacetylcholine (BrACh)) on the neurone. On the native neurone BrACh caused a strong reversible increase in membrane conductance, being only 3–5 times less active than ACh; quaternary ammonium *N*-alkyl derivatives of maleimide were very weak agonists (3–4 orders less effective than ACh) and NEM did not excite ChRM at all. It was not possible to restore the ACh-sensitivity to the initial level with DTBCh after application of an alkylating agent to DTT-treated neurone membrane. These results underline the important role of disulphide bonds in the ACh-induced conductance changes of neurone membrane which has been shown for both electroplax and skeletal muscle preparations.

BrACh seems to cause the irreversible depolarisation of electroplax membrane pretreated with DTT<sup>15</sup>, but this has not been observed with *Aplysia* neurones<sup>9</sup> and we have never observed this effect with *Limnaea* neurones. In addition, the responses of neurone membrane to ACh and BrACh decreased approximately to the same extent after DTT pretreatment. These data suggest that BrACh cannot activate reduced AChRs of mollusc neurone membrane.

We have tested cholinergic antagonists and agonists for the ability to protect ChRM against DTT-induced modification. The specific competitive nicotinic antagonist, *d*-tubocurarine ( $1 \times 10^{-3}$  M) completely blocked response to supramaximal ACh concentrations (up to  $1 \times 10^{-4}$  M) but did not prevent the modification of ChRM by DTT. In contrast to this unexpected finding high ACh concentrations effectively protected ChRM against the action of DTT (Fig. 2).

One explanation of the difference in *d*-tubocurarine and ACh protecting abilities may be that the molecules of these two cholinergic agents interact with different sites in AChR so that ACh produces a steric hindrance for DTT attack on disulphide bond, but *d*-tubocurarine does not. Alternatively, binding of ACh molecule to the AChR active site might evoke a conformational transition of AChR which would protect the disulphide bond from reduction; binding of *d*-tubocurarine would not induce such a conformational change.

In order to test the first hypothesis we compared the protecting ability of two pairs of drugs: tetramethylammonium (TMA)–phenyltrimethylammonium (PhTMA) and decamethonium–diphenyldecamethonium. The first agent of each pair is a cholinergic agonist, the second drug (a structural analogue of the other) does not excite but blocks the receptors effectively. Neither PhTMA nor diphenyldecamethonium protected ChRM against DTT-reduction, while their exciting analogues, TMA and decamethonium, partially blocked the effect of DTT (Table 1). It seems highly unlikely that the drugs with such similar chemical structures as TMA and PhTMA or decamethonium and diphenyldecamethonium should bind to different sites on AChR. A direct correlation between the activity of agonists and the ability to prevent the modifying action of DTT was found (Table 1). ACh,

**Table 1** Effect of cholinergic ligands on AChR inactivation induced by DTT

Ligand	Relative efficiency of exciting action*	Concentration used to protect against DTT (M)	Extent of protection†	Relative efficiency of protection against ‡
ACh	1	$1 \times 10^{-5}$	0.60 (5)	1
TMA	0.02	$1 \times 10^{-4}$	0.64 (3)	0.107

\* Calculated by the ratio of the equieffective concentrations relying upon increase in ChRM conductance.

† Calculated by the formula  $(c-b)/(a-b)$  where  $a$  = response to a standard ACh concentration in control;  $b$  = response to the same ACh concentration after DTT treatment;  $c$  = response to standard ACh concentration after treatment with DTT + protector. No. of experiments given in parenthesis.

‡ Calculated by the ratio of protection extent and protector concentration.

TMA and decamethonium therefore seem to protect AChRs by inducing a transition in AChR to another conformation when the agonist binds with the active site; in the new conformation the disulphide bond becomes inaccessible to DTT action.

Thus our results suggest that it is the receptor molecule alone that DTT modifies to cause inactivation of ChRM.

In all experiments involving the use of agonists as protectors DTT was added into the perfusing medium when almost all the AChRs were desensitised (Fig. 2). Presumably the AChR active site conformational change protecting the disulphide bond against reduction corresponds to the desensitisation but not to the excitation. This suggestion seems quite likely according to data on conformational transition of AChRs revealed by fluorescent dyes in membrane fragments of electric organs<sup>16,17</sup> in the presence of high (desensitising) agonist concentrations. To test this possibility we compared the DTT action in the presence and absence of ACh after 2 min exposure of the neurone to a high ACh concentration. In the latter case ACh was washed out with physiological solution containing DTT when desensitisation was complete (Fig. 3). A considerable fraction of AChRs was shown to be still in desensitised state during the first 1.5–2 min after ACh was removed from the perfusing solution. In these conditions DTT inactivated ChRM as strongly as it did in the complete absence of a protector. Apparently, for successful protection, the AChR–agonist complex must exist.

We therefore conclude first, that AChR does not lose its affinity

**Fig. 3** Inactivation of ChRM by DTT treatment immediately after removal of ACh ( $1 \times 10^{-5}$  M) from the perfusing solution. Control experiments ensured that responses to a standard ACh concentration were very much reduced in 1.5–2 min after washout of ACh  $1 \times 10^{-5}$  M (a result of desensitisation). 1 And 3, Responses to ACh  $2 \times 10^{-6}$  M; 2, response to conditioning ACh concentration ( $1 \times 10^{-5}$  M).

to agonists in the desensitised state; and second, the active site of the receptor in both the activated (non-desensitised) and the desensitised states can experience a conformational transition when interacting with an agonist molecule; the disulphide bond is hidden as a result of this process.

Desensitisation of *Limnaea* neurone membrane has been shown not to be due to changes in the system of ionic transport through the excited ChRM<sup>18</sup>. Considering these data and our results we suppose that the desensitisation of *Limnaea* neurone membrane is due to the specific state of a unit coupling the excited active site of AChR and ChRM ionophore.

We thank Mrs Olga Shvirst for helpful comments.

## Cellular regulation of an allosteric modifier of fish haemoglobin

ADENOSINE TRIPHOSPHATE (ATP) is the major organic phosphate in the red blood cells of a wide variety of fish species<sup>1–4</sup>. Its role as an allosteric modifier of fish haemoglobins is similar to that of 2,3-diphosphoglycerate (2,3-DPG) in mammalian red blood cells, in that it decreases the affinity of haemoglobin for oxygen<sup>5,6</sup>. After exposure to the anoxia of high altitude or in certain conditions of anaemia, mammals increase red blood cell 2,3-DPG to facilitate oxygen unloading at the tissues<sup>7</sup>. By contrast, eels have been shown to decrease erythrocyte organic phosphate (that is, ATP) and increase haemoglobin–oxygen (Hb–O<sub>2</sub>) affinity when acclimated to low environmental oxygen<sup>8</sup>. To test if this phenomenon was expressed in another fish species, we acclimated *Fundulus heteroclitus*, a euryhaline minnow, to hypoxic conditions. Our finding that this fish also lowered red blood cell ATP by as much as 40% (Fig. 1) suggests that this is a general response to hypoxia among water-breathing vertebrates.

The mechanism by which hypoxic fish lower red blood cell ATP *in vivo* is unknown. We predicted that if the control mechanism was directed at the erythrocyte level, then fish red blood cells should decrease ATP, *in vitro*, in anoxic conditions. Consistent with our *in vivo* observation, we found that anaerobic *F. heteroclitus* red cells significantly lowered their ATP levels *in vitro* (Fig. 2). Since the nucleated erythrocytes of fish possess mitochondria, we reasoned that this response may be mediated by way of a decrease in oxidative phosphorylation. This hypothesis was supported when aerated cells were incubated in the presence of low concentrations of cyanide. This inhibitor of aerobic respiration reduced intracellular ATP to levels similar to those found in the anoxic cells (Fig. 3). Thus, it seems that one reason fish have retained a functional oxygen-consuming electron transport system in the

Fig. 1 Time course of acclimatization of *F. heteroclitus* to hypoxic (●) and normoxic (○) conditions at 22 °C. Dissolved oxygen values were 1.5–2.0 p.p.m. for hypoxic and 8.5–9.0 p.p.m. for control fish. Red blood cell ATP for this experiment and all others described in this paper were determined using the firefly luciferase assay<sup>9</sup>. All points represent averages of 6–7 fish. Bars indicate  $\pm$ s.e.m.

mitochondria of their red blood cells is to control the levels of haemoglobin allosteric effector.

Glycolytic inhibition experiments are consistent with the cyanide data (Fig. 3). With iodoacetate, an inhibitor of glyceraldehyde 3-phosphate dehydrogenase (GAPDH), reducing equivalents from glycolysis are not available for oxidation by the mitochondrial electron transport chain and less pyruvate is oxidised in the tricarboxylic acid (TCA) cycle. Consequently, red blood cells exposed to this inhibitor lower their ATP to levels nearly equal to those of cyanide-poisoned cells. In the presence of fluoride, which inhibits enolase, the red blood cells show concentrations of ATP only slightly lower than control levels since reducing equivalents are formed during the earlier GAPDH reaction which can then fuel mitochondrial oxidative phosphorylation.

Assuming that iodoacetate and fluoride are acting as specific inhibitors in the red blood cells, these data indicate that the small amount of reducing equivalents from glycolysis would be nearly identical to that resulting from a fully functioning TCA cycle. Since no data exist on the relative contributions of glycolysis and the TCA cycle to the production of reduced nicotinamide adenine dinucleotide in fish erythrocytes, one cannot be certain of the intracellular potential to oxidise pyruvate. In fact, the information reported here suggests that the TCA cycle may play a substantially smaller role in fish red blood cell mitochondria compared with other tissues. We are currently investigating this possibility.

Since a physical dependence exists between oxygen solubility and water temperature (oxygen concentration is 12.5 p.p.m. at 10 °C compared with 7.5 p.p.m. at 30 °C), our observation that *F. heteroclitus* lowers red blood cell ATP when acclimated to elevated temperatures (group I, Table 1) prompted us to ask if this response was triggered by reduced oxygen (as in our hypoxic experiments), increased temperature, or both of these variables. Therefore, fish were acclimated to various temperatures (10 °C, 22 °C, and 30 °C), but with oxygen concentration maintained

Fig. 2 ATP/Hb molar ratio in *F. heteroclitus* red blood cells incubated in anaerobic (●) and aerobic (○) conditions. Cells were washed three times in PBS (pH 7), and then maintained in a medium containing physiological concentrations of inorganic salts and glucose buffered at pH 7.5 as described elsewhere<sup>9</sup>. Values are from duplicate determinations which did not vary by more than 6%.

Fig. 3 ATP/Hb molar ratio in fish red blood cells incubated in media at pH 7.5 with no inhibitor (○),  $10^{-2}$  M NaF (■),  $5 \times 10^{-4}$  M iodoacetate (▲) or  $10^{-4}$  M NaCN (●). Values are from duplicate determinations which did not vary by more than 5%.

constant (about 7 p.p.m.) at each temperature. These animals also decreased their erythrocyte ATP with increased temperature (group II, Table 1). Moreover, fish acclimatised to 10 °C, but in air saturated water (12.5 p.p.m.), showed the same red blood cell ATP levels as those maintained at 10 °C but with 7 p.p.m. oxygen (Table 1). These data demonstrate that the ATP response was elicited by increased temperature alone and was independent of dissolved oxygen levels in the range 7–12.5 p.p.m.

Table 1 Comparison of red blood cell ATP/Hb molar ratios in *F. heteroclitus* acclimatised to different temperatures

Temperature (°C)	Group I	Group II
10	1.84 ± .05	1.81 ± .07
22	1.68 ± .06	1.72 ± .08
30	1.31 ± .08	1.29 ± .06

In group I, dissolved oxygen values at the various temperatures were: 10 °C, 12.5 p.p.m.; 22 °C, 9.0 p.p.m.; and 30 °C, 7.5 p.p.m. The dissolved oxygen for group II was maintained at a constant value of 7.0 p.p.m. during the course of the acclimatisation (4 weeks). All values represent averages of 10–12 fish. Errors are reported as  $\pm$  s.e.m.

As outlined earlier, there is a significant ATP response when isothermal hypoxia is induced (that is, below 3 p.p.m.). Under hypoxia, *F. heteroclitus* also increased the number of circulating red blood cells (haematocrit) by 40%. This phenomenon has been reported and discussed previously for other fish species<sup>8</sup>. In an earlier study, we reported a significant increase in the haematocrit of warm-acclimatised *F. heteroclitus*<sup>11</sup>. In the present study, however, we found no difference in haematocrit between fish acclimatised to different temperatures. In addition, red blood cell ATP concentrations of 30 °C-acclimatised fish (see Table 1) were higher than those described previously<sup>11</sup>. To simulate natural conditions, oxygen levels were not controlled in our earlier study. Therefore, biological oxygen demand (microbial activity, and so on) at the higher temperature probably lowered dissolved oxygen into the hypoxic range. In these conditions, which *F. heteroclitus* often encounter in their natural habitat, temperature and oxygen act in tandem to control red blood cell organic phosphate and, in turn, Hb-O<sub>2</sub> affinity. When governed solely by its physical dependence on temperature, however, dissolved oxygen never reaches the low values required to induce hypoxia.

## Thyroidal trophic influence on skeletal muscle myosin

CROSS-INNervation experiments have convincingly demonstrated the importance of the nerve in determining the differential properties of skeletal muscle myosin. The role of hormones in deciding the phenotypic character of muscle myosin has received considerably less attention than that of the neural factors. Recent studies have shown that short-term alterations in thyroid status results in significant changes in cardiac muscle myosin<sup>1–4</sup>. In contrast, some of those investigations also used skeletal muscle, but no apparent effects on skeletal muscle myosin were detected<sup>2,4</sup>. But the greater half-life of skeletal muscle myosin would require a longer time than cardiac myosin to manifest these changes<sup>5</sup>. We have studied the effects of longer term hypothyroidism and hyperthyroidism on skeletal muscle myosin. We report here that alterations in thyroid status influence the quality of skeletal muscle myosin. Our observations suggest possible thyroidal involvement, along with or through neural trophic factors, in determining the phenotypic properties of skeletal muscle myosin.

Normal, hypothyroid and hyperthyroid male Sprague-Dawley albino rats with initial body weights of 180–200 g were subjects. Thyroidectomised animals were purchased from Hormone Assay (Chicago). Hyperthyroidism was induced in thyroidectomised rats by subcutaneous injections of 30 µg per 100 g body weight of Na 3,3',5 triiodo-L-thyronine on alternate days for six weeks. Animals were killed by exsanguination under pentobarbital anaesthesia (60 mg per kg). Thyroid status of the animals was confirmed by the enzyme activities of  $\alpha$ -glycerolphosphate dehydrogenase (EC 1.1.99.5)<sup>6</sup> and succinate dehydrogenase (EC 1.3.99.1)<sup>7</sup> from whole homogenates of liver and soleus muscle at 25 °C (Table 1).

Immediately after excision a mid-portion of the soleus muscle was prepared for histochemistry. The tissue was mounted and frozen in isopentane cooled with liquid nitrogen. Cross-sections of 10-µm thickness were cut at –20 °C and stained for myofibrillar adenosine triphosphatase (M-ATPase). The staining procedure involved 10 min pre-incubation (37 °C) in glycine or 2-amino-2-methyl-1-propanol buffer (pH 10.30) containing 18 mM CaCl<sub>2</sub> followed by 30 min incubation in pre-incubation medium containing 3.08 mM ATP and adjusted to pH 9.40. This is essentially the method of Padykula and Herman<sup>8</sup> as modified by Guth and Samaha<sup>9</sup>. The difference in staining intensity is based on the alkali stability and lability of fast and slow skeletal muscle myosin ATPase activity, respectively<sup>9,10</sup>, resulting in a more intense stain for fast than slow muscle fibres at an alkaline pH.

Soleus muscles used for myosin isolation were pooled into groups of four and stored in glycerol at –20 °C. Myosin was prepared using the method of Bárány and Close<sup>11</sup>. The yield of myosin protein was similar for each experimental group (Table 1). Mg<sup>2+</sup>-activated ATPase activity indicated minimal actin contamination (1.06 nmol per mg protein per min). Ca<sup>2+</sup>-stimulated myosin ATPase activity was determined at 37 °C at various pH values using the reaction mixture of Bárány and Close<sup>11</sup> and the inorganic phosphate assay of Rockstein and Herron<sup>12</sup>. Protein determinations were by the Lowry method with bovine albumin as the standard<sup>13</sup>.

Histochemical observations indicate that thyroid status

Table 1 Effects of thyroid status on soleus muscle myosin

	Euthyroid	Hypothyroid	Hyperthyroid
Final body weight (g)	385±6 (14)	297±6 (14)*	242±8 (8)*
Liver			
SDH activity	24.86±0.79 (11)	18.07±0.84 (11)*	36.10±3.29 (7)*

†Statistically significant at  $P < 0.01$ .

can alter the proportion of alkali stable (fast) and labile (slow) M-ATPase fibres in rat skeletal muscle (Fig. 1). The soleus muscles from the hypothyroid animals consisted of <1% alkali-stable fibres as compared to 16% for the euthyroid muscles (Table 1). Whereas the hyperthyroid muscles were comprised of more than twice the percentage of alkali-stable fibres observed in the euthyroid muscles. Muscles of each group contained fibres with an intermediately intense M-ATPase stain. These fibres were most prevalent in the hyperthyroid muscles. They were classified as alkali-stable fibres in the present study.

The pH profiles of myosin ATPase activity are shown in

Fig. 1 Transverse sections from the soleus muscle of a, euthyroid b, hypothyroid and c, hyperthyroid rats stained for myofibrillar ATPase (×22).

Fig. 2. The greatest differential effect on enzyme activity between the experimental groups was observed at pH 10.30. At this alkaline pH the euthyroid soleus exhibited only 54% of its activity at pH 7.40 as compared to 12% for the hypothyroid muscles and 236% for the hyperthyroid muscles. When comparing the activities at pH 10.30, the hypothyroid muscles had only 27% the activity of the euthyroid muscles. Whereas the hyperthyroid had a fivefold greater activity than the euthyroid muscles and 20-fold more activity than the soleus muscles of the hypothyroid animals at that alkaline pH.

As in the histochemical procedure, the basis for resolving fast-twitch and slow-twitch myosin ATPase is its property of being alkali resistant and susceptible, respectively<sup>10</sup>. The change in the alkaline stability of myosin isolated from hypothyroid and hyperthyroid muscles clearly shows that this property of the myosin protein has been transformed and that the transformation occurs in both directions, depending on the thyroid state. These biochemical findings, besides quantifying the changes in ATPase activity, have confirmed the histochemical observations for these experimental conditions. This is important since in certain conditions the histochemical method of staining for M-ATPase can be misleading<sup>14,15</sup>. Further evidence for the validity of the M-ATPase stain was a complete reversal of the staining intensity of fast and slow fibres at pH 4.35, as occurs in normal muscle. The close agreement between the percentage increase in alkali-stable fibres (19%) and myosin ATPase activity (39%) at pH 7.40, considering fast-twitch myosin has three times the specific catalytic activity of slow-twitch myosin, imparts further credibility to the M-ATPase stain. This comparison, however, is not as highly correlated for the hypothyroid muscle.

It is well documented that fast-twitch and slow-twitch muscle myosin are qualitatively distinct proteins<sup>10,11,16</sup>. It is widely accepted that these differences in myosin are primarily regulated by neural factors<sup>9,11,16,17</sup>. Our results indicate that the thyroid state of an animal also has the potential for determining the phenotype of skeletal muscle myosin. The extent of the changes in myosin ATPase activity in soleus muscles which had been hyperthyroid for only six weeks was similar to that of changes observed in soleus muscle following long-term (6–15 months) cross-innervation with a fast nerve<sup>11,16,17</sup>. Bárány and Close<sup>11</sup> observed a 50% increase in soleus myosin ATPase at pH 7.40 following 10–15 months of cross-innervation with a nerve normally innervating a fast-twitch muscle, as compared to a 39% increase for the hyperthyroid soleus. At pH 10.0, cross-innervated soleus muscle had a 125% increase in ATPase activity as compared to 70% for the hyperthyroid soleus at

Fig. 2 % of Ca<sup>2+</sup>-activated myosin ATPase activity relative to 100% for the euthyroid muscle at pH 7.40. The euthyroid soleus muscle at pH 7.40 at 37 °C had an activity of 0.18  $\mu$ mol per mg myosin protein per min.

pH 10.30. In other studies<sup>16,17</sup> the soleus exhibited increases of 35–75% in myosin ATPase (pH 7.8–8.0) 6–12 months following cross-innervation, whereas the hyperthyroid soleus had 186% greater activity than the euthyroid at pH 8.00. Furthermore, the extent of this transformation is probably not fully manifest in this six-week time period in the hyperthyroid muscle but it is probably nearly complete in the long-term cross-innervation studies. Longer term studies are in progress to allow for the changes to become more fully established, along with the added purpose of further categorising the changes in the myosin protein.

The findings of this investigation offer little insight into the mechanism by which the thyroid state alters the character of skeletal muscle myosin. It is possible the thyroidal influence directly and selectively stimulated muscle gene expression, affected neural trophic regulation, or produced other hormonal imbalances which induced this transformation.

## Hydrolysis of polyesters by lipases

INCREASING public concern about the treatment of waste materials has stimulated the study of the biodegradation of synthetic polymers. Among synthetic polymers, aliphatic polyesters are generally known to be susceptible to biological attack<sup>1–5</sup>, but there are few reports of enzymes involved in their degradation. Bell *et al.*<sup>6</sup> recently showed that the molecular weight of polycaprolactone (PCL) decreases on exposure to the acid protease from *Rhizopus chinensis* for 6–10 d (decreasing from 13,000 to 10,000). In addition, Tabushi *et al.*<sup>7</sup> have found that polyesters composed of phenyllactic acid and lactic acid are hydrolysed by  $\alpha$ -chymotrypsin. We showed previously that a polyester-degrading enzyme from *Penicillium* sp. strain 14-3, purified to a homogeneous state as exhibited by ultracentrifugal analysis and polyacrylamide gel electrophoresis, has properties resembling lipase<sup>8</sup>. It was not previously recognised that lipase acts on polyesters. We report here that several commercial lipases and an esterase also hydrolyse polyesters, and that *Rh. delemar* lipase is capable of hydrolysing various kinds of polyesters.

PCL and polypropiolactone were prepared by ring opening polymerisation of  $\epsilon$ -caprolactone<sup>9</sup> and  $\beta$ -propiolactone respectively in benzene in a nitrogen atmosphere at 60 °C with a diethylzinc–water catalyst system. Poly- $\beta$ -methylpropiolactone (poly- $\beta$ -hydroxybutyrate) was made from  $\beta$ -methylpropiolactone by the method of Yamashita *et al.*<sup>10</sup> with a triethylaluminium–water catalyst system. Other saturated aliphatic polyesters were synthesised by a melt polycondensation technique<sup>11</sup>, and unsaturated polyesters were synthesised by high temperature solution polycondensation<sup>12</sup>. All alicyclic and aromatic polyesters were from Nihon Chromat except poly (tetramethylene terephthalate), from Union Carbide. The number average molecular weight ( $\bar{M}_n$ ) was measured by the vapour pressure equilibrium method with a Hitachi 117 apparatus.

Fig. 1 Gas chromatograms of the hydrolysis products of PEA by *Rh. delemar* lipase. PEA powder was filtered from the reaction mixture which was then analysed (a). The concentrated and dried reaction mixture was then esterified with diazomethane in ether (b). The hydrolysate of (a) with alkali was also analysed (c). Chromatographic conditions: Shimadzu GC-5A (flame ionisation) with glass column (1 m  $\times$  0.3 cm internal diameter) packed with Tenax GC. Temperature programmed at 5° per min from 135° to 345 °C (dashed line). Flow rate of both nitrogen and hydrogen was 50 ml per min. Arrows indicate ethylene glycol (EG) and adipic acid (AA).

Table 1 Hydrolysis of polyesters by lipases

		TOC concentration (p.p.m.)			
Enzyme control		Formed by hydrolysis of polyester			
		Poly (ethylene adipate)	Poly-caprolactone	Poly(cyclohexylene-dimethyl succinate)	Poly(2,2-dimethyl-trimethylene isophthalate)
<i>Achromobacter</i> sp.	10	880	110	60	0
<i>Candida cylindracea</i>	5	3900	70	0	0
<i>Geotrichum candidum</i>	10	140	0	0	0
<i>Rhizopus arrhizus</i>	10	7400	60	40	0
<i>Rhizopus delemar</i>	5	6100	110	70	0
Hog liver (esterase)	30	940	90	120	0
(Substrate control)	—	(330)	(150)	(70)	(20)

Each reaction mixture contained 400  $\mu$ mol of phosphate buffer (pH 7.0), 300 mg of the polyester powder (particle size less than about 1 mm) and enzyme in a total volume of 10 ml. The enzyme concentration in each reaction mixture was adjusted to a degree of hydrolytic activity capable of liberating 420  $\mu$ mol of fatty acid from olive oil per 60 min at 37 °C at pH 7.0 (see ref. 8). Reaction mixtures were incubated on a rotary shaker at 180 r.p.m. at 30 °C for 16 h. After incubation, the TOC concentration was measured. No effect of the interaction between each substrate and inactivated enzyme preparation was observed. For example, when *G. candidum*, *Rh. arrhizus* or *Rh. delemar* lipase which was treated with a boiling water for 10 min, was allowed to react with PEA (PCL), the TOC concentrations in the filtrate of the reaction mixtures were 340 (150), 340 (160) and 330 (150) p.p.m. respectively as compared with 330 (150) p.p.m. of substrate control. The effect could not be examined in hog liver esterase because it was insolubilised by the heat treatment.

*Achromobacter* sp. and *Candida cylindracea* lipases (Meito Sangyo) were purified by gel filtration on Sephadex G-100 (2.6  $\times$  79 cm) from crude preparations. Ultracentrifugally homogeneous preparations of *Geotrichum candidum* and *Rh. delemar* lipases were from Seikagaku Kogyo and partially purified preparations of *Rh. arrhizus* lipase and hog liver esterase were from Boehringer Mannheim Yamanouchi.

Hydrolysis of polyesters was measured by the rate of their solubilisation, and the measurement process does not necessarily involve complete hydrolysis into the constituent parts. The rate was determined by measuring the water-soluble total organic carbon (TOC) concentration at 30 °C in the reaction mixture using a Toshiba-Beckman TOC analyser. The precise reaction rates of polyester hydrolysis cannot be determined by this method, however, since the polyester powder particles in the reaction mixture vary in size and the solubility of the oligomers

formed by polyester hydrolysis differs depending on the kind of polyester. In the substrate and enzyme controls, enzyme or substrate was omitted from the reaction mixture.

Aliphatic polyesters, poly(ethylene adipate) (PEA) and PCL were hydrolysed by lipases from various microorganisms and hog liver esterase with the results shown in Table 1. *Rh. arrhizus* and *Rh. delemar* lipases showed especially strong activity. The action of hog liver esterase on PEA produced much more adipic acid and ethylene glycol, constituents of PEA, than did lipases. This suggests that the biodegradable property of aliphatic polyester comes from its susceptibility to hydrolysis by lipases or esterases. An alicyclic polyester, poly(cyclohexylenedimethyl succinate), was also hydrolysed by lipases from *Achromobacter* sp., *Rh. arrhizus* and *Rh. delemar* and by hog liver esterase. Of these, hog liver esterase showed the strongest activity. In contrast, an aromatic polyester, poly(2,2-dimethyl-

Table 2 Hydrolysis of polyesters by *Rh. delemar* lipase

Polyester	Mn	Powder size	TOC concentration (p.p.m.)	
			Substrate control	Formed by lipase
Poly(ethylene adipate)	2,720	C	330	8,360
Poly(ethylene suberate)	4,050	B	250	1,020
Poly(ethylene azelate)	4,510	B	570	3,080
Poly(ethylene sebacate)	1,570	A	390	550
Poly(ethylene decamethylate)	1,610	B	100	180
Poly(tetramethylene succinate)	4,240	A	270	150
Poly(tetramethylene adipate)	1,790	B	520	3,360
Poly(tetramethylene sebacate)	2,440	A	130	980
Poly(hexamethylene sebacate)	5,820	B	40	380
Poly(2,2-dimethyltrimethylene succinate)	2,370	A	360	240
Polypropiolactone	4,270	A	580	2,240
Poly-DL- $\beta$ -methylpropiolactone	8,190	E	250	10
Polycaprolactone	6,740	A	150	310
Poly( <i>cis</i> -2-butene adipate)	2,700	C	1,270	580
Poly( <i>cis</i> -2-butene sebacate)	6,190	B	130	300
Poly( <i>trans</i> -2-butene sebacate)	3,560	A	910	340
Poly(2-butyne sebacate)	4,930	C	210	670
Poly(hexamethylene fumarate)		A	60	35
Poly( <i>cis</i> -2-butene fumarate)		B	390	30
Poly(tetramethylcyclobutane succinate)	3,440	E	10	0
Poly(cyclohexylenedimethyl succinate)	3,910	B	70	130
Poly(cyclohexylenedimethyl adipate)	3,250	B	80	200
Poly(tetramethylene terephthalate)		C	0	0
Poly(ethylene tetrachlorophthalate)	1,670	A	0	0
Poly(2,2-dimethyltrimethylene isophthalate)		A	20	0

All polyesters but two were prepared into powders at 30 °C by grinding. The exceptions were poly(tetramethylene terephthalate) which was powdered with a centrifugal ball mill and polycaprolactone which was powdered from a solution in chloroform by a precipitation method. The particle size of each polyester powder was ranked A, B, C, D or E, corresponding respectively to roughly less than 0.25 mm, less than 0.50 mm, less than 1.0 mm, 0.25–1.5 mm, 0.25–3 mm. Each reaction mixture contained 400  $\mu$ mol of phosphate buffer (pH 6.0), 300 mg of the polyester powder and 0.3 mg of *Rh. delemar* lipase in a total volume of 10.0 ml. The reaction mixtures were incubated in the same way as Table 1. The TOC concentration of the enzyme control was 10 p.p.m.

trimethylene isophthalate), was not hydrolysed by any of the enzyme preparations.

*Rh. delemar* lipase purified to homogeneity in the ultracentrifuge was found capable of hydrolysing various kinds of polyesters (Table 2). PEA was the best substrate tested, and activity was relatively high with poly(ethylene azelate). Polypropiolactone and PCL were degraded, but not poly(DL-β-methylpropiolactone), the D-isomer of which is known to be one of the materials stored by bacteria and algae. Unsaturated polyesters from 2-butenediol were also degraded, but polyesters with even a few hybrid bonds among the polymer chains, such as those induced from poly(hexamethylene fumarate) and poly(cis-2-butene fumarate), were hardly degraded. Two alicyclic polyesters, poly(cyclohexylenedimethyl succinate) and poly(cyclohexylenedimethyl adipate), were degraded fairly extensively. Aromatic polyesters such as poly(tetramethylene terephthalate), poly(ethylene tetrachlorophthalate) and poly(2,2-dimethyltrimethylene isophthalate) were not degraded.

Amongst the products of PEA hydrolysis by *Rh. delemar* lipase, we detected not only the constituent parts of PEA—adipic acid and ethylene glycol—but also large quantities of PEA oligomers (Fig. 1). This may indicate that *Rh. delemar* lipase randomly splits ester bonds.

## Involvement of DNA gyrase in bacteriophage T7 DNA replication

NOVOBIOCIN and the related antibiotic coumermycin A<sub>1</sub> (referred to as coumermycin) inhibit the supercoiling of circular double-stranded DNA catalysed by *Escherichia coli* DNA gyrase<sup>1</sup>. They also inhibit the replication of chromosomal DNA in *E. coli* cells<sup>2</sup>, and of circular double-stranded DNA in cell-free systems from *E. coli*<sup>3–6</sup>. The activity of DNA gyrase obtained from a coumermycin-resistant (*cou<sup>r</sup>*) mutant and the replication of colicin E1 plasmid (*Col E1*) DNA in a cell extract of the mutant are resistant to both drugs<sup>7</sup>. These results show that DNA gyrase is an essential component of these systems for the replication of the circular double-stranded DNA. It is interesting to examine whether DNA gyrase also has a role in replication of linear double-stranded DNA. The DNA of *E. coli* bacteriophage T7 is linear and double stranded<sup>8</sup>. Linear replicating molecules have been isolated from infected cells and it has been claimed that the phage DNA replicates as a linear form, at least in the first round of replication<sup>9</sup>. We show here that the replication of phage T7 DNA, including the first round, is inhibited by coumermycin.

The effect of various concentrations of coumermycin on DNA synthesis in coumermycin-sensitive and resistant bacteria during 30 min after infection of phage T7 was examined. T7 DNA synthesis was inhibited by coumermycin, to a greater extent in the sensitive bacteria than in the resistant bacteria (Fig. 1). To attain a similar extent of

inhibition, an approximately 10 times higher concentration of the drug was needed for the resistant bacteria than for the sensitive bacteria. At a given concentration of the drug, T7 DNA synthesis was inhibited to about the same extent as chromosomal DNA synthesis in the uninfected cells. This was true of both the sensitive and the resistant bacteria. On the other hand, it has been shown that a 50-fold lower concentration of the drug is sufficient to produce comparable inhibition in toluene-treated cells (refs 4, 13 and unpublished results). Thus the T7-infected cells seem to retain the same limited permeability to the drug as the uninfected cells. Phage DNA synthesis (Fig. 1) and chromosomal DNA synthesis (data not shown) in the resistant bacteria were inhibited by high concentrations of coumermycin. It is known that high concentrations (25 μg ml<sup>-1</sup> or higher) of coumermycin significantly inhibit DNA gyrase purified from the resistant bacteria (M. Gellert, personal communication) as well as other enzymes, such as DNA polymerase III and DNA-dependent RNA polymerase of *E. coli*<sup>14</sup>. The resistant strain used in this experiment was selected as a spontaneous drug-resistant mutant and its mutation was mapped close to the *dnaA* locus by P1-mediated transduction. Moreover, when *bglC<sup>+</sup>* (the *bgl* locus is known to be located near the *dnaA* locus<sup>14</sup>) transductants of the resistant strain were selected, about 20% of them were found to be simultaneously coumermycin-sensitive, and two representative drug-sensitive transductants showed a drug-sensitivity of T7 growth similar to that of the

**Fig. 1** Effect of coumermycin on DNA synthesis in T7-infected cells. NI746 (●), a low thymine-requiring mutant of NT525 *Su-bglC<sup>+</sup>cou<sup>r</sup>* and its spontaneous coumermycin-resistant (*cou<sup>r</sup>*) derivative, NI751 (○) were used. The *cou<sup>r</sup>* mutation of NI751 was mapped close to the *dnaA* locus. DNA synthesis in toluene-treated cells of NI751 and *Col E1* DNA replication in an extract of this strain were resistant to coumermycin. Cells were grown to  $3 \times 10^8$  per ml in OC medium (a minimal medium with casamino acids (Difco))<sup>10</sup> supplemented with thymine 2 μg ml<sup>-1</sup> at 37°C, centrifuged and suspended in one-tenth volume of the adsorption buffer (10mM Tris-HCl, pH7, 1mM MgCl<sub>2</sub>, 0.5% NaCl, 10 μg ml<sup>-1</sup> gelatin, 0.4% casamino acids) with various concentrations of coumermycin (from J. Davies, University of Wisconsin). Coumermycin was dissolved in dimethyl sulphoxide and an equal amount of the solvent was added to the control cultures. Bacteria were infected with phage T7 at a multiplicity of five by incubating for 7 min at 30°C. The adsorption mixtures were diluted 10-fold in OC medium with <sup>3</sup>H-thymine (1.2 Ci mmol<sup>-1</sup>, NEN) and various concentrations of the drug. After incubating at 30°C for 30 min, acid-insoluble radioactivity in 0.1 ml of each culture was determined<sup>10</sup>—100% corresponds to about 12,000 c.p.m. A DNA-DNA hybridisation experiment<sup>11</sup> was performed with the samples made from the infected sensitive and resistant bacteria incubated with or without 100 μg ml<sup>-1</sup> coumermycin. In the sample made from the sensitive bacteria without the drug and those from the resistant bacteria with or without the drug, more than 80% of the labelled material was phage T7 DNA, whereas 75% was bacterial DNA in the sample made from the sensitive bacteria with the drug (data not shown). It is known that bacterial DNA synthesis does not stop immediately by T7-infection<sup>12</sup>, and it is also known that bacterial DNA synthesis does not stop immediately after addition of coumermycin<sup>2</sup>.

Fig. 2 Kinetics of DNA synthesis by T7-infected cells of NI746-*cou*<sup>+</sup> (a) and NI751-*cou*<sup>+</sup> (b). Methods used were generally as described in Fig. 1. Cells were grown in OC medium supplemented with thymine ( $2 \mu\text{g ml}^{-1}$ ), centrifuged and suspended in the adsorption buffer with (○) or without (●) coumermycin ( $100 \mu\text{g ml}^{-1}$ ). The cells were then infected with phage T7 at a multiplicity of five. After incubation for 7 min at  $30^\circ\text{C}$ , mixtures were diluted in the same medium with  $^3\text{H}$ -thymine ( $1.2 \text{ Ci mmol}^{-1}$ ) and incubated at  $30^\circ\text{C}$ . After incubation for 10 min, the culture of the infected sensitive bacteria without the drug was divided into two portions, to one of which coumermycin ( $100 \mu\text{g ml}^{-1}$ ) was added and incubation was continued (△). At intervals aliquots (0.1 ml) were withdrawn and acid-insoluble radioactivity was determined.

sensitive strain used in this experiment. Therefore, the possibility that the observed resistance of T7 growth to the drug was due to some unidentified drug-resistant mutant enzyme which might be involved in T7 growth should be very scarce. The differential effect of the drug on T7 DNA synthesis in the sensitive and the resistant bacteria indicates that the inhibition of the activity of DNA gyrase by coumermycin caused the inhibition of T7 DNA synthesis in the sensitive bacteria.

DNA gyrase could act directly on T7 DNA molecules, or it could act on the bacterial chromosome to produce and maintain its negatively supercoiled structure, which might be necessary for T7 DNA replication. When coumermycin  $100 \mu\text{g ml}^{-1}$  was added at the beginning of infection, DNA synthesis in the infected sensitive bacteria was severely inhibited (Fig 2a), whereas that in the resistant bacteria was relatively less inhibited (Fig. 2b). A similar inhibition of DNA synthesis in the infected sensitive bacteria was observed when the drug was added 10 min after infection (Fig 2a). Since the bacterial chromosomes are extensively broken down by that time<sup>15</sup>, the inhibition of T7 DNA synthesis is not likely to be an indirect effect due to action of the drug on the bacterial chromosomes. This in turn shows that DNA gyrase acts on T7 DNA molecules.

To determine whether even the first round of replication of T7 DNA molecules is inhibited by coumermycin, the fate of the parental DNA after infection was examined. In this experiment, T7am233 (gene 6) was used with a multiplicity of infection of less than one to eliminate possible complexities in the analysis due to recombination and concatemer formation. It is known that neither recombination nor formation of concatemers of T7 DNA occurs in the absence of a functional gene 6 product, although several rounds of semiconservative DNA replication take place<sup>16-18</sup>. Both the sensitive and resistant bacteria incubated for 20 min in 5-bromodeoxyuridine (BrdUrd)-supplemented medium were infected with  $^{32}\text{P}$ -labelled T7am233 and incubated for 12.5 min at  $30^\circ\text{C}$  with or without  $100 \mu\text{g ml}^{-1}$

coumermycin. DNA was extracted and analysed by equilibrium CsCl density gradient centrifugation. For the DNA prepared from the infected sensitive bacteria incubated without the drug, most of the labelled DNA appeared at the position of fully light (LL) DNA, and about 25% formed a broad band with a peak approximately at the position of half-heavy (HL) DNA (Fig. 3a). The shoulder on the heavier side of HL DNA probably consists of replicative intermediates in the second or later round of replication. T7am233 DNA replication in each infected cell was quite heterogeneous. The DNA replication of T7am<sup>+</sup> as well as a gene 6 amber mutant has been shown to be rather heterogeneous in the experiments similar to that shown here; a considerable portion of the parental DNA still forms a band at the position of LL DNA, even when the progeny DNA labelled with BrdUrd appears at the position of fully heavy (HH) DNA, and replicated DNA molecules form rather broad bands at the positions of HL and HH DNA<sup>16,17</sup>. For the DNA prepared from the infected sensitive bacteria incubated with coumermycin, however, practically no labelled DNA appeared in the position of HL DNA (Fig. 3c). In contrast, when the resistant bacteria were used, the amount of labelled DNA

Fig. 3 CsCl density gradient centrifugation of DNA extracted from cells of NI746-*cou*<sup>+</sup> (a and c) and NI751-*cou*<sup>+</sup> (b and d) infected with  $^{32}\text{P}$ -labelled T7am233. Cells were grown in OC medium supplemented with thymine ( $2 \mu\text{g ml}^{-1}$ ), centrifuged and suspended in OC medium supplemented with BrdUrd ( $5 \mu\text{g ml}^{-1}$ , Sigma) in place of thymine and further incubated for 20 min at  $37^\circ\text{C}$  to replace the intracellular pool of nucleotides. Cells were then centrifuged, suspended in the adsorption buffer with (c and d) or without (a and b) coumermycin ( $100 \mu\text{g ml}^{-1}$ ), and infected with  $^{32}\text{P}$ -labelled ( $40 \text{ mCi mmol}^{-1}$ ) T7am233 (phage strain obtained from H. Ogawa, University of Osaka) at a multiplicity of 0.6. After incubation for 5 min at  $30^\circ\text{C}$ , the cultures were diluted in OC medium supplemented with BrdUrd and with or without the drug, and incubated at  $30^\circ\text{C}$ . At 12.5 min after the dilution, the reaction was stopped by addition of four volumes of cold SSC ( $0.15 \text{ M NaCl}$ ,  $0.015 \text{ M Na}_2\text{ citrate}$ )- $5 \text{ mM KCN}$ . Cells were centrifuged and suspended in  $0.2 \text{ ml}$  of SSC (pH adjusted to 8.0)- $10 \text{ mM EDTA}$ - $10 \text{ mM KCN}$ . Lysozyme (Sigma) was added at a concentration of  $500 \mu\text{g ml}^{-1}$  and the mixtures were frozen and thawed three times. After incubation for 15 min at  $37^\circ\text{C}$ , sodium *N*-lauroyl sarcosinate (Sigma) was added at a concentration of  $0.1\%$  and the mixtures were incubated for 15 min at  $65^\circ\text{C}$ . The cell lysates were then treated with proteinase K ( $200 \mu\text{g ml}^{-1}$ , E. Merck) at  $37^\circ\text{C}$  for 2 h. The lysates were diluted with SSC and after addition of  $^3\text{H}$ -labelled ( $2.5 \times 10^4 \text{ c.p.m.}$ ) *E. coli* DNA, brought to a final volume of  $7.5 \text{ ml}$  with a density of  $1.73 \text{ g ml}^{-1}$  by adding CsCl. They were centrifuged in a Beckman 40 rotor for 50 h at  $36,000 \text{ r.p.m.}$  at about  $15^\circ\text{C}$ . Each gradient was collected from the bottom of the tube to give about 50 fractions, and  $^{32}\text{P}$  (○) and  $^3\text{H}$  (●) counts were determined. Approximately 80% of the input radioactivity was recovered from each gradient. Positions for light (LL), half-heavy (HL) and heavy (HH) DNA are indicated by the arrows. In c, the distribution of  $^{32}\text{P}$  and  $^3\text{H}$  counts in the fractions 18-35 is also shown on a 10-fold expanded scale.

which formed a band around the position of HL DNA was only slightly reduced by the addition of the drug (Fig. 3b, d). These results indicate that the inhibition of replication of T7am233 DNA molecules in the sensitive bacteria was due to inhibition of DNA gyrase by coumermycin.

The inhibition of the first round of replication could occur at initiation and/or at an early stage of DNA replication. In the preparation made from the infected sensitive bacteria incubated with the drug, a small but significant amount of labelled DNA was found between the positions of HL DNA and LL DNA (see Fig. 3c inset), even though practically no band of the labelled DNA was found in the positions of the HL or heavier DNA. These molecules are likely to be replicative intermediates arrested by the drug early in replication, rather than those on the way of the normal replication resulting from the incomplete inhibition by the drug of the initiation of DNA replication. This leads to the conclusion that DNA gyrase is involved at least in the stage of elongation of DNA chains.

Phage T7 DNA has redundant ends and could circularise through that structure<sup>19</sup>. Circular molecules have been only rarely observed in T7am<sup>+</sup> DNA obtained from bacteria at an early stage of infection, however (refs 2, 9 and unpublished results of T. Ogawa and J.T.). Use of T7am233 reduced the possibility of circularisation of phage DNA molecules mediated by the product of gene 6. Because the DNA of T7am<sup>+</sup> as well as a gene 6 amber mutant<sup>17</sup> seems to replicate as a linear molecule, the inhibition of the first round of replication of T7am233 DNA molecules by coumermycin implies that DNA gyrase is involved in the replication of linear double-stranded DNA.

When a duplex DNA molecule replicates, the parental strands must unwind to serve as templates. If the replicating molecule is circular and covalently closed, at least a temporary nicking of one of the strands is essential for the unwinding. On the other hand, if the replicating molecule is linear, the unwinding could be accomplished by relative rotation of the replicated region in relation to the unreplicated region of the molecule without nicking of the strands. But, such rotation for unwinding of a long duplex DNA molecule *in vivo* is quite improbable, if one considers the necessity of simultaneous rotation of molecules attached to the DNA molecule, such as the machinery for transcription and translation and cellular structures like membranes<sup>20</sup>. It has been suggested that phage T7 DNA in infected cells is associated with the bacterial membrane<sup>21-23</sup>. The unwinding could be facilitated by nicking and closing of one strand which would occur at or a little ahead of the replicating point. A nicking and closing enzyme may act to relieve the positive supercoiling strain imposed by replication, or more actively, to facilitate separation of the parental strands by imposing a negative supercoiling strain. DNA gyrase would be a suitable enzyme to act in this process.

We thank M. Gellert for useful comments.

## Is the centriole bound to the nuclear membrane?

THE persistence of the centriole during interphase near the nucleus within the so-called cell centre seems to be a general feature of most animal cells. An association between the nucleus and the cell centre has been proposed and has been clearly shown in some cell types<sup>1,2</sup>. A permanent system involving chromosomes, spindle fibres and centrioles has been suggested by Lettre *et al.*<sup>3</sup>, and Aronson<sup>4</sup> has demonstrated the existence of a Colcemid-sensitive mobile system between the nucleus and a centre at the two-cell stage in the sea urchin *Lytechinus variegatus*. We show here that there is a physical association between the centriole and the nucleus in the rat liver cell which resists cold treatment, cell disruption and nuclear isolation. When nuclear envelopes are prepared from isolated nuclei, the association between the centriole and the nuclear envelope is maintained.

Nuclei from rat liver were prepared according to Blobel and Potter<sup>5</sup> with slight modifications to adapt the procedure to larger amounts of tissue. Liver tissue (33 g) was homogenised in 110 ml of 2.2 M sucrose-TKM (50 mM Tris-HCl pH 7.5, 25 mM KCl, 5 mM MgCl<sub>2</sub>) with a Chauveau type homogeniser (Plastimarne). The homogenate was filtered through 10 layers of cheese cloth and mixed with 220 ml of 2.2 M sucrose-TKM, using a glass rod. The suspension was transferred to cellulose nitrate tubes underlaid with 10 ml of 2.3 M sucrose-TKM and centrifuged for 1 h at 4 °C and 25,000 r.p.m. in an SW 25.2 rotor (Beckman). The nuclei were then washed by resuspension with 1 M sucrose-TKM and with 0.25 sucrose-TKM.

These nuclear preparations were pure as judged by electron microscopy. Nuclei showed intranuclear structures such as nucleoli and perinuclear and perinucleolar chromatin. The nuclear envelope was present, contained pores and had ribosomes associated with the outer leaflet. The chemical composition of these preparations was constant, suggesting good reproducibility of the isolation technique. The lipid phosphorus/DNA phosphorus ratio was  $0.060 \pm 0.002$  (over 20 determinations). This value is low, indicating a low cytoplasmic contamination. Presence of centrioles in such nuclear preparations was not detected by electron microscopy (although we did not make a systematic search using serial sections).

Nuclear envelopes were isolated from such nuclei by the use of heparin which, in suitable conditions, induces complete solubilisation of chromatin<sup>6,7</sup>. This allows the observation of well-preserved nuclear envelopes which have not been damaged by sonication, high salt or shearing through sucrose gradients. Nuclei were resuspended in 0.01 M Tris-HCl pH 8.0 containing 0.01 M Na<sub>2</sub>HPO<sub>4</sub> at a final concentration of 200 µg DNA per ml. Heparin was then added in an excess corresponding to 1.5 times (w/w) the amount of DNA present in the nuclear suspension. After short vortex mixing the nuclear suspension was diluted five times with buffer and nuclear membranes were sedimented by centrifugation for 40 min at 20,000 r.p.m. (45,000g). All operations were performed at 4 °C.

Electron microscopic observation of such nuclear envelopes showed a surprisingly high number of centrioles. Some examples

Fig. 1 Presence of centrioles in nuclear membrane pellets. Rat liver nuclei were resuspended at 4 °C in 0.01 M Tris-HCl pH 8.0 containing 0.01 M  $\text{Na}_2\text{HPO}_4$  and incubated with heparin ( $\text{Na}^+$  salt-grade I from Sigma) at a heparin to DNA ratio of 1.5 (w/w). After short vortexing, the nuclear suspension was diluted fivefold with buffer; nuclear membranes were sedimented immediately in that case at 45,000g for 40 min. Nuclear membrane pellets were fixed with 2% glutaraldehyde in 0.1 M cacodylate buffer, pH 7.4. They were postfixed in 2% osmium tetroxide, dehydrated in ethanol and embedded in Epon-Araldite. *a-d*, 42,000  $\times$ ; *e, f*, details showing apparent attachment (small arrows) of centrioles to membranes through dense material surrounding them. *e*, 60,000  $\times$ ; the large arrow indicates a nuclear pore. *f*, 72,000  $\times$ .

are shown in Fig. 1. They sometimes seemed to be bound to the nuclear envelope by the surrounding material (Fig. 1*e-f*). We assumed that the failure to see centrioles in preparations of whole isolated nuclei was due to the relative size of centrioles compared to nuclei. Such a difficulty should not occur with optical microscopy which allows the observation of whole nuclei. Isolated nuclei, suspended in the isolation buffer (0.05 M Tris-HCl, pH 7.5, 0.025 M KCl, 0.005 M  $\text{MgCl}_2$ ) showed irregular shapes, intranuclear organisation and nucleoli when observed by phase contrast microscopy. It remained difficult to detect the presence of centrioles in these nuclei.

The ability of low  $\text{Mg}^{2+}$  ( $5 \times 10^{-4}$  M) to decondense heterochromatin<sup>8,9</sup> was exploited to produce swollen and spherical nuclei with homogeneous nucleoplasm, in which all apparent organisation is lost except faint nucleoli. In such conditions, it was easy to detect centrioles associated with nuclei either by phase contrast microscopy or in polarised light. Several examples are given in Fig. 2. More than 50% of the nuclei in any pre-

paration had a centriole which could be recognised without ambiguity because of its typical aspect as two paired dots in phase contrast microscopy or polarised light microscopy. In rare circumstances, centrioles could be seen as two orthogonally oriented small bars (Fig. 2*f, j*); change in focus could show centrioles as black dots or refringent white dots (Fig. 2*e, i*). With some nuclei, by changing the focus, one could observe the centriole as two white dots, two black dots, a white and a black dot and the reverse situation (Fig. 2*e*). This is because of the complex spatial arrangement of centriole in two orthogonally oriented bars. In some cases varying the focus caused one or two other dense spots to appear on the same nucleus (Fig. 2*g, h, i*), but the meaning of this observation is not known.

In some nuclei, fibrillar structures could be seen originating in centriole. This would suggest the existence of an 'aster-like' system in the liver cell, and that part of it may remain associated with centriole during cell disruption and cold treatment.

Fig. 2 Examples of rat liver nuclei resuspended at low magnesium concentration (0.05 M Tris-HCl pH 7.5, 0.025 M KCl,  $5 \times 10^{-4}$  M  $MgCl_2$ ) which show associated centrioles. Magnification is  $2,100 \times$ . Arrows indicate centrioles. *a-h*, Phase contrast microscopy; *i-l*, polarised light; *e* and *i*, various focusings on the same nucleus which show that centrioles can appear as two dark dots, two refringent dots or one dark and one refringent dot. *f* and *j*, centrioles appearing as two orthogonally-oriented bars. *g* and *h*, nuclei showing other dark dots (dotted arrows) beside centrioles.

This association centriole-nucleus is probably not restricted to the liver cell, as it was also seen in preparations of thymocyte nuclear membranes.

What is the significance of these observations? A major role has been attributed to the cytoskeleton in the control of cellular functions such as cell shape, cell movements, cell polarity and cell surface activity. This raises the question of the exact role of the association of the microtubule organising centre with centrioles during interphase.

One role for such a binding between nucleus and centriole could be the anchorage of nucleus into the cell cytoplasm. The methods introduced by Prescott *et al.*<sup>10,11</sup> to enucleate cells make use of cytochalasin B, and enucleated cytoplasts obtained in this way always contained centrioles<sup>12-14</sup>. One can therefore speculate that it is the disruption of the binding of nucleus to centriole which allows cell enucleation, although an alternative hypothesis has been proposed by Wright *et al.*<sup>15</sup> which makes the subplasmalemmal network of microfilaments the target of the cytochalasin B effect. The effect of cytochalasin B suggests that the binding of the nucleus to the centriole is at least in part realised by actin filaments. That not only actin is involved is indicated by the effect of colchicine<sup>1</sup> and colcemid<sup>2</sup> on the centriole-nucleus complex.

The well-known biological effect of cytochalasin B on cell cultures is to impair cytokinesis but not karyokinesis, leading to bi- or multi-nucleated cells<sup>15</sup>. Thus, the structural role proposed

here for the nucleus-centriole complex, that is, anchorage of the nucleus into the cell, would indeed have a functional counterpart.

## Islands in space

R. L. F. Boyd

*The High Frontier: Human Colonies in Space.* By G. K. O'Neill. Pp. 288. (Jonathan Cape: London, 1977.) £5.95.

A POPULATION of several thousand million people located in space colonies, within a mere 35 years of the initiation of a space colonisation programme, is typical of the thinking—one might even say the evangel—of Dr O'Neill. In this readable and extraordinarily optimistic promotion of the cause of space as better than this Earth the author argues that man must be persuaded to rid himself of his "planetary chauvinism" and accept that even the Moon or Mars, for example, would not provide as suitable an environment as man-made habitats situated at one of the semi-stable Lagrangian points in the Earth-Moon system.

Three stages of development are suggested. "Island One" would be constructed primarily of aluminium and glass inside a sphere of 0.5 km diameter. The habitat, filled with an oxygen atmosphere, would rotate to provide an Earthlike gravity at the equator. The great majority of materials for the construction would be mined and transported from the lunar surface. Heavy industry, located nearby outside the sphere, and agriculture would, it is claimed, benefit from the continuous and predictable supply of solar energy, and the whole system could support a population of 10,000 in some comfort. Careful screening would prevent any unwanted "bugs" from being taken in from Earth; and presumably no malign mutation is expected to occur.

Within a further 50 years, the scale of development from these small beginnings is envisaged as leading to the "Island Three" habitats, cylinders 4 miles in diameter and 20 miles in length, maintaining several million inhabitants. There is probably no reason to dispute that such a design is already within the limits of present-day structural materials. Economic motivation for such colonies is claimed to lie with the construction of large solar power stations, subsequently placed into geosynchronous orbit and providing the Earth with electricity through high power microwave transmission. Such systems have, of course,

already been the subject of detailed design studies under NASA sponsorship, but it is not clear why sunlight in space should be more economic than in the desert areas of the near tropic latitudes here.

This book may properly rank as space fiction rather than prophecy but if so it is not because of any violation of scientific laws. No fundamentally new physics is required nor any great projection of present-day engineering practice. The speed with which such plans could be formulated and implemented even if adequate political backing was forthcoming, as suggested by O'Neill, is a point on which opinion will, however, vary greatly. In particular, there is little discussion of the inevitable sociological, legal and personal, including moral and religious, questions in their widest sense.

Much space is devoted to the projected economic aspects of space colonisation, particularly in terms of the initial investment, and to considering the viability of selling power to Earth through the solar power stations, considerations inevitably of a very speculative nature and, in themselves, hardly a complete justification for this mammoth scheme.

In chapter 2, entitled "The Human Prospect on Planet Earth", O'Neill presents what he sees as the most compelling arguments for a massive

colonisation of space. The shortage of land and energy on Earth are even now an obvious cause for concern and, with the expected rate of population growth, the situation may become desperate even before the middle of the next century. It may be thought, however, that these are basically political and ethical questions, that given good will, unselfishness, honesty, education, tolerance, sympathy and so on, it would be no more difficult to build a heaven on Earth than a "New Earth" (the title of chapter 4) in the heavens.

The New English Bible translates an aspiration of the early Christian church from two millenia ago, and no doubt echoing a far older yearning of many people, as "we . . . look forward to new heavens and a new Earth, the home of justice". This problem with its associated need for wisdom and moral fibre outweighs all the technical difficulties we face. Solve this and we might avoid the energy crisis of the late 1980s and the serious risk of war between "haves" and "have-nots" before the end of then century. □

## Animal cells in culture

*Biochemical Methods in Cell Culture and Virology.* By Robert J. Kuchler. Pp. ix+331. (Halsted/Wiley: New York and Chichester, UK, 1977.) £22.50; \$38.

BECAUSE research in animal virology is based to a large extent on the use of animal cells in culture, it might seem a good idea to include in one manual the procedures of both. In fact, the task is not an easy one, as this review will suggest.

The stated aim of this book is to provide a guide for growing, handling and studying viruses and cell cultures in the hope that the student considering a career in virology, cell biology or cancer research should find it useful. There are three parts, of about equal lengths: Cell Culture, Virology, and

Macromolecular Analysis. The content is essentially a collection of very many procedures. Each procedure, or group of related procedures, is preceded by a brief introduction on its purpose and, very cursorily, on its history.

Not many students can secure a copy of the standard procedures, formulations, recipes, and so on, which several large research laboratories, dealing with virology and cell cultures, necessarily keep. These procedures are often collected in loose-leaf Laboratory Manuals. Every time that a procedure or formulation is changed, it is an easy matter to replace the corresponding pages.

The next best method (though expensive) for a student who cannot get hold of any such manual, is a book; but a book does not have replaceable

loose pages. In the two fields of virology and cell culture the speed of advance of methods is very fast, much faster than that of ideas. Thus, a manual on methods requires continuous updating.

Even the short time between going to press and publication has had this undesirable effect. Two examples: the procedures for cell fusion stop at the (doubtfully practical) use of lysolecithin (1972); that is, before the introduction of polyethyleneglycol; and in the section on "Macromolecular Analysis", sequencing of viral DNA genomes by means of restriction endonucleases is not even mentioned.

This book thus falls between two stools. As a manual on methods it is, inevitably, already outdated in parts and will very soon become extensively so. As a general survey of viruses as probes for cell biology its aim is not

wide or high enough. Perhaps fewer methods, just as examples, but a much deeper and wider discussion on the current problems of virology and on how those methods contributed to solving them, would have made the book more stimulating. The student is much more helped by making him interested enough to look up the literature on procedures than by providing him with ready-made recipes of very short half-life. As it is, this book will be more valuable as a source of references in the libraries of research laboratories than as a laboratory manual at the bench, or as reading for postgraduate students.

## Mammalian fertilisation mechanisms

*Fertilization Mechanisms in Man and Mammals.* By Ralph B. L. Gwatkin. Pp.x+161. (Plenum: New York and London, 1977.) \$21.

FERTILIZATION is intrinsically a tremendously important process, marking as it does the union of male and female gametes, the recombination of their genetic loads, and the initiation of the new individual. Only in comparatively recent times, however, have various aspects of fertilisation in mammals become susceptible to direct experimentation. The earlier work was consequently restricted largely to non-mammalian forms, notably the marine invertebrates. This area of investigation has continued to be most productive and is now experiencing a recrudescence of research interest, which, together with studies based on the new capabilities in the handling of mammalian gametes, is yielding a wealth of new information. The time is ripe for an up-to-date and critical collation of published data from both mammalian and non-mammalian sources. Gwatkin's book goes a long way to meeting this challenge and should certainly fill a need.

Chapters in the book deal with the development and properties of the gametes, their transport in the female tract, fertilisation *in vitro*, sperm capacitation, the acrosome reaction, sperm penetration of the zona pellucida, sperm-egg fusion, the defence against polyspermy, pronucleus formation and the metabolic events detected during fertilisation. Additionally, atten-

tion is given briefly to the fate of surplus spermatozoa in the female tract and their interaction with somatic cells, and to the results of recent work on parthogenesis. There is also an Epilogue in which the author indicates directions for future research.

In the relevant chapters, particular attention is given to the exploration of the surface properties of gametes using lectins and other agents, and the close study of the successive stages of interaction of egg and spermatozoon which betoken different orders of response. A good deal of mystery still attaches to these processes and this in itself should serve as a powerful stimulus to further research. A fascinating feature of this phase of fertilisation lies in the apparent duplication of gamete properties and faculties, which denotes a curious limitation in the forms of substrate on which the influence of evolution has had to operate. The consolation for the biologist lies in the possibility of drawing useful inferences from what can be regarded as complementary patterns.

The book is written in a clear concise style and bears the authoritative stamp of an active and highly productive investigator in the field. The wide range of the author's acquaintance with the literature is evident throughout the text and in the extensive list of references provided.

The book can be warmly recommended to all those involved in research on gamete physiology and fertilisation, in non-mammals as well as mammals, and as an essential source of information and ideas for advanced students of medical and biological sciences.

## Resource and Environmental Sciences Series

**General Editors: Sir Alan Cottrell FRS and Professor T. R. E. Southwood FRS**

A new series of texts catering for the needs of the growing number of students taking environmental science courses at university and providing excellent reference for A-level students.

The series will provide a range of basic texts on environmental biology, chemistry, ecology, economics and physics, recognising that students will enter their degree studies with widely varying scientific backgrounds.

The main group of books in the series will then build on this foundation.

*The first two titles in the series are:*

### Energy Resources

**J. T. McMullan, R. Morgan and R. B. Murray**

*Publication November  
Paper £3.50*

### Environmental Economics

**An Introduction for Students of the Resource and Environmental Sciences**

**Sir Alan Cottrell FRS**

*Publication January  
Paper £1.95*

**Edward Arnold**

## Logical foundations of computation

*The Theory of Computer Science: A Programming Approach.* By J. M. Brady. Pp. xiii+276. (Wiley: New York and London, 1977.) Hardback £8; paperback £4.50.

BRADY has written a book which can be warmly recommended to readers wishing to understand the logical foundations on which computation rests. It will be particularly valuable to students of computer science, but may be of interest also to computer programmers who wish to widen their horizons.

As a practical discipline, computing grew up in the late 1950s and early 1960s. Recruits to the programming profession came from mathematics, engineering, science, and even the classics and humanities. These people applied a largely intuitive approach to solving problems pressed upon them by commercial and other users, urgently requiring effective solutions. There were many difficulties, and many projects were late in completion, cost more

than was intended, or were even aborted before completion. The lessons learned during this period led to the formulation of a set of methodologies for program design and construction which are now often graced with the name "Software Engineering".

To aid the newly emerging discipline, theoretical foundations have been and are being developed. Methods of defining the syntax and semantics of programming languages, methods of proving the correctness and equivalence of programs, and of analysing the complexity of algorithms, are theoretical developments with immediate potential impact.

Arising, however, from the mathematics and logic camp there has come a theoretical background to computing which is often criticised as quite irrelevant to the practising programmer. Brady argues that this is due to a misunderstanding of its position in the logical structure of the subject. The theories of computability, based on Abstract (Turing) Machines and General Recursive Functions belong to the meta-theory the goals of which are to define precisely the meaning of 'computable' and to discover the theoretical limits of computability.

His book is accordingly divided into

two parts. Part 1 covers the meta-theory, whereas part 2 (which has a different title in the contents list and in the text) discusses the approach to a theory of computer science.

Brady does not assume extensive mathematical knowledge of his readers, and the prerequisites are summarised in an appendix. Throughout the book he leans heavily on the intuitions of the reader as an experienced programmer. He compares his approach with that of M. L. Minsky (*Computation: Finite and Infinite Machines*, Prentice-Hall 1967) by suggesting that his book is to programming what Minsky's is to hardware; hence the second part of his title. He writes with an enthusiastic style which makes his text very readable. There are frequent invitations to the reader to extend his understanding by proving lemmas and solving problems. These he calls "checkpoints", a usage which I find irritating. There are also more typographical errors than one expects in a book of this quality. These are, however, minor blemishes in an otherwise excellent book.

S. J. Goldsack

*S. J. Goldsack is Professor of Computing Science at Imperial College of Science and Technology, University of London, UK.*

## Neutrino proceedings

*Proceedings of the International Neutrino Conference, Aachen 1976.* Edited by H. Faissner, H. Reithler and P. Zerwas. Pp. xii+748. (Vieweg: Braunschweig, 1977.) DM168.

It has been interesting to review this conference report while attending the 1977 Lepton-Photon Symposium in Hamburg, which covers the same field and much more. Rather than making last year's news seem old and dull, this year's conference illustrates how useful the Aachen proceedings can be as a reference. Aachen was a specialised conference and the speakers had time to do their experiments and theories justice. At conferences with a wider spread of subject matter the results can be reported but the details are lost.

Some of the results reported at Aachen have, of course, now been overtaken by better experiments, or modified by more careful analysis. Nevertheless, much of the picture is the same as it was last year. The four-quark theory, with charm, still stands and a great deal of the evidence for this is reported in these proceedings; including a few wisely chosen non-neutrino results from  $e^+e^-$  storage rings. The quark-parton picture of

hadrons is being increasingly refined, with about the correct amount of scale-breaking to satisfy the asymptotically free gauge theories. As well as data on these effects there is a useful review by the late Benjamin Lee, who includes a simple introduction to scale-breaking in the course of his final summary of the whole conference.

Theoretical contributions from Dalitz, Cabibbo, Salam and others give a picture of the variety of different quark models still available. M. K. Gaillard and de Rujula discuss the success of the charm concept in the light of the rich spectrum of particles reported in the experimental sessions. In contrast to their confidence, there are calls from Wolfenstein, from Fritsch and from Sakurai for more data on neutral currents, on second class weak currents, on neutrino oscillations, on parity violation in atomic physics, and so on. We certainly do not yet understand the weak interaction completely.

As well as high energy accelerator physics, there are a few papers on neutrino astrophysics and on assorted low-energy topics such as double  $\beta$  decay, and the  $^3\text{H}$  spectrum as a probe of the neutrino mass.

David J. Miller

*David Miller is Lecturer in Physics at University College, London, UK.*

## Prosimian behavioural ecology

*Ecology and Behaviour of Nocturnal Primates.* By P. Charles-Dominique. Pp. x+277 (Duckworth; London; Columbia University Press: New York, 1977.) £12.50; \$21.90.

THE behavioural ecology of the prosimians, an essential element in our understanding of the evolution of the order of Primates as a whole, raises special problems not encountered in field studies of monkeys and apes. The majority of prosimians are small, shy inhabitants of dense forest environments, solitary in their active phase and, most pertinent here, nocturnal. The task of adequately studying these in the wild is daunting and might seem impossible at times. Yet this book is a measure of just how successfully that task can be carried out.

In the main, it presents the results of almost a decade of research in Gabon in West Africa on five sympatric species of lorid (three bushbabies, the potto and the angwantibo) living in the equatorial rainforest. Covering in great detail such areas as feeding and diet, stratification, locomotion, defence against predators, and many aspects of social behaviour and demography, it is concerned not simply with each species viewed in isolation but with the vital questions arising from their sympatry. It succeeds in shedding considerable light on the evolution of this group, the adaptive strategies called forth by the particular and precise ecological niches they occupy, the specialisations of structure and behaviour that have developed, and especially the manner in which competition between the species has been minimised.

In most instances, penetrating and wide-ranging analysis leads to well-rounded and convincing synthesis. This has been achieved in two ways: first, by the skilful use of a variety of field techniques, ranging from direct observation with headlamp to capture-mark-release procedures and radio-tracking, the latter yielding some most valuable information. Second, the author repeatedly recognises or finds confirmation of his emergent hypotheses in acute 'casual' observations of untrammelled animals, or in beautifully simple manipulations of the forest environment or captive circumstances.

All this is not to say that Charles-Dominique's account of the Gabonese prosimians is complete or without fault. In places, a paucity of hard data, unrevealed sample sizes or the absence of detail when procedures are des-

cribed, raise doubts in the mind. The repertoires of communicatory and some other behaviours are incomplete and the social significance of play in lorids is totally overlooked. Moreover, certain interpretations are suspect or erroneous—for example, that concerning the defensive posture of *Arctocebus*, and the view that the primary function of the prosimian dental comb is gum collection rather than grooming, despite the indisputable importance of the former function in *Euoticus*, so clearly shown here.

The title, if not the subtitle of the book could be misleading if, by it, one were led to expect a thorough-going review of our knowledge of all nocturnal primates. In this respect, the work is erratic and there are some surprising omissions, even within the narrower compass of the Loridae. A concluding chapter does attempt to place nocturnal primates among the diurnal forms in a wider perspective, but here again the

quality of the result is decidedly uneven, marred by the dubious validity of a number of contentions regarding Primate evolution and ecology. Thus, the idea that competition for food is necessarily eliminated or even reduced by a Box-and-Cox temporal partitioning of an ecological niche does not stand up to close scrutiny as a general truth.

The strength of this book, and it is indeed strength, lies in the author's approach to, and resolution of, the problems of behavioural ecology in his Gabonese prosimians; and in his demonstration that no aspect or detail of structure or behaviour is arbitrary, without meaning in terms of the animal's survival. That is reason enough to commend this volume.

Gilbert H. Manley

*Gilbert H. Manley is Lecturer in Primate Biology in the Department of Anthropology at the University of Durham, UK.*

## Sound waves in solids

*Sound Waves in Solids.* By H. F. Pollard. Pp. 366. (Pion: London; Academic: London, 1977.) £10.50.

THE author of this latest addition to the rapidly growing literature of acoustics is Dr Howard F. Pollard who is an Associate Professor in charge of the Physical Acoustics Laboratory at the University of New South Wales in Sydney, and is the leading Australian worker in this field. The objective of the author, as indicated in the introduction, is to provide initially the necessary theoretical background for the reader to appreciate fully the various applied fields of acoustics, such as non-destructive testing. This practical aspect is kept well to the fore throughout the book, and uniquely the author introduces, after the basic theory, synopses of experiments which appropriately illustrate the problem under discussion. A particular usefulness of the text to the student is the provision of sets of questions at the end of each chapter which are based on the problems included at the end of specified sections of the foregoing subject matter. A full set of solutions to the book.

In considering the general contents of the book, it is the chapter on acoustic waveguides on which the author can be particularly congratulated. He has introduced this important topic through the simpler system of a fluid waveguide, and, having established the essential theory and con-

cepts, he deals with the understanding of the various practical applications. The chapter on ultrasonic experimental techniques is quite comprehensive and the latest developments such as ultrasonic spectrometry receive adequate recognition. The author's own research involvement in such work enriches his presentation of the subject; this also applies to the chapter in the book concerned with the exciting field of acoustic visualisation. A representative number of holographic applications are given, and here the author has revealed his musical interests by the inclusion of some reconstructions at audiofrequencies.

The problem of the choice of references is difficult in a field like solid-state ultrasonics, which is large and rapidly expanding, but the author has helped the reader by including the appropriate references at the end of each chapter. Moreover, those concerned with particular experiments are given with the text. An author and a subject index are also included. The line diagrams are very clear and also the text, although the use of smaller print for experimental descriptions gives an impression of over compression.

The title is indicative of the breadth of the subject so efficiently and clearly discussed by the author, and the book deserves to be welcomed alike by students, teachers and research workers.

R. W. B. Stephens

*R. W. B. Stephens is Senior Visiting Research Fellow at Chelsea College, University of London, UK.*

# newly on the market

These descriptions are prepared by the staff of *Nature* on the basis of material provided by manufacturers. The Reader Enquiry Card faces the inside cover.

**Microprocessor-controlled logger.** Pye Unicam. The Philips PM 4000 system is designed for logging voltages, currents and temperatures; later models will handle mechanical (strain) measurements directly. Up to 950 channels can be controlled by one unit, and remote control and operation of the data logger are possible. The main-frame unit can hold up to 50 channels with extension units for each additional 100 channels. Extension units can be up to 10 m from the control unit—the use of digital communication between mainframe and extension units eliminates noise problems. Results can be conditioned into the relevant engineering units using internal linearisation tables and formatted for internal or external presentation. Programming is reduced to a simple question-and-answer dialogue using a built-in keyboard and integral alphanumeric display, and no special programming language is necessary. Completed programs can be dumped out to, or dumped in from, a digital cassette recorder enabling custom program libraries to be built up.

Circle No. 45 on Reader Enquiry Card

**Single-test creatinine analyser.** Beckman. The new Creatinine Analyzer-2 automates precise measurements of creatinine in plasma, serum, urine, or amniotic fluid. Time from sample injection to final readout is 26 s compared with the 15 min usually required for running the test manually. Creatinine is clinically important in determining kidney function, in monitoring renal dialysis therapy, and as a warning of incipient muscular disease such as muscular dystrophy and hypothyroidism. Operation of the Creatinine Analyzer-2 is based on the Jaffe reaction. Colour is generated as the patient sample mixes with reagent under controlled temperature conditions, and the analyser measures the rate of colour change, which is a more precise indicator of creatinine than endpoint analysis.

**Sample-handling system for radioimmunoassay.** Beckman. The modular Phase I RIA sample-handling system is designed to improve radioimmunoassays by simplifying procedures for rapid, accurate, inexpensive analyses. Stand-alone instruments, accessories, and packaged RIA kits make up the system, which is available as a whole or in parts. Phase I system includes the Gamma 4000 gamma spectrometer, which is capable of processing up to 400 samples automatically; an on-line DP-5000 microprocessor data reduction system, which stores up to 10 RIA data reduction programs including counts per minute; the Model J-6 Centrifuge; and an all-in-one pipettor/diluter/dispenser which allows the solid-phase Beckman RIA Kits to be run with only one simple pipetting step. Basic to the Phase I System are Beckman double-antibody, solid-phase RIA kits, which reduce incubation time, centrifugation requirements, and chance for error.

**Blood bank refrigerator.** Forma. The Forma Scientific model 3880  $\pm 4^\circ\text{C}$  blood bank refrigerator has a 300-bag capacity and features top-to-bottom temperature uniformity within  $0.5^\circ\text{C}$  in compliance with nationally recognised standards. Standard equipment includes six 50-bag capacity roll-out storage drawers with label holders, a self-charging battery alarm system with alarm ringback and remote alarm contacts, a pressure writing temperature recorder, automatic condensate removal (to eliminate drain lines), and a 100% stainless steel interior cabinet with cabinet lights. The unit is 30 inches wide, 28 inches deep, and 73 inches high.

Circle No. 48 on Reader Enquiry Card

**Thermomechanical analyser.** Perkin-Elmer. The Model TMS-2 thermomechanical analyser when used for the thermal characterisation and quality control of materials, determines precisely and rapidly, dimensional changes (expansion and extension modes) or visco-elastic changes (penetration and compression modes) of small samples in any form—powder, pellet, film, fibre or moulded part. The Model TMS-2 system consists of analyser, analyser control and heater control modules. Displacement can be recorded simultaneously as either integral or derivative signal, both individually attenuated and filtered. The linear variable differential transformer is in complete thermal isolation from the furnace, which permits operation at very high sensitivity with flat baselines over a broad temperature range. Heating and cooling rates from  $-170^\circ\text{C}$  to  $+325^\circ\text{C}$  are possible with the standard furnace and an optional low temperature furnace is available. A sliding furnace assembly, positive positioning of probe on sample and open tube design facilitates ease of sample handling.

Circle No. 49 on Reader Enquiry Card

**Automated blood gas analyser.** Technicon. The Technicon BG II, pH/blood gas system uses an advanced, built-in computer to help provide accurate answers on eleven parameters on blood samples as small as  $130\ \mu\text{l}$ . Small samples give the instrument wide application in hospital critical care facilities where patients with severe burns and other major illnesses are treated. These patients, as well as infants and the very elderly, have frequently been incapable of giving a large enough sample in the past. The Technicon BG II system is extremely easy to operate and maintain. With the BG II, the hospital can have cost-effective coverage in the central laboratory as well as in any other areas where blood gas samples are processed. The results of the eleven tests are available in  $2\frac{1}{2}$  min, and are printed out on paper tape or multiple-copy ticket. The values for pH,  $\text{PCO}_2$ ,  $\text{PO}_2$ , and haemoglobin are measured directly: standard base excess, base excess, standard bicarbonate, bicarbonate,  $\text{O}_2$  saturation,  $\text{O}_2$  content, and total  $\text{CO}_2$  are computed and printed out simultaneously.

**Electronic precision balances.** Mettler. A compact, rugged housing is used for two new electronic precision balances. The PL1200 can weigh up to 1,200 g with a readability of 0.01 g and the PL200 can weigh up to 220 g with 0.001 g readability. An automatic stability detector circuit monitors the zero point and indicates when a reliable weighing result is available for reading. The measuring cycle can be adjusted from the outside in four different steps. This allows the balance to adapt to difficult weighing problems (such as restless lab animals) and to prevailing environmental conditions without affecting its weighing performance. The capabilities of weighing below the balance and of measuring moisture loss with the help of the LP12 infrared dryer are also built into these balances. Printers, weight-count converters and other peripheral instruments can also be connected by means of a BCD output.

Circle No. 51 on Reader Enquiry Card

Mettler PL1200

**Interferometer.** Metals Research. The new Metals Research interferometer has been developed for the examination of the transmission characteristics of laser rod materials both for zonal selection and final quality assessment. Following the classical lines of the Twyman-Green Interferometer the instrument is packaged so as to provide a sample space of 40 mm diameter, 200 mm long. Folding the light path in an optimum manner gives a table-top instrument of only 20×11×10 inches, weighing approximately 110 pounds. Accuracy is 1/20 wave. Special design features include built-in laser illumination to provide high contrast fringes for critical viewing of small apertures (6 mm dia.), and a decohering filter (rotating disk) to suppress spurious fringes created within the system. A built-in Polaroid roll film holder takes 1:1 photographs of specimen patterns.

**Automatic analyser for nitrogen oxides.** Pye Unicam. The Philips PW 9762 analyser continuously and automatically measures atmospheric oxides of nitrogen (NO, NO<sub>2</sub>, or their sum NO<sub>x</sub>) in a simple and economic manner, and it will do so for up to 3 months without intervention. NO and NO<sub>x</sub> are both measured in identical samples of ambient air, NO<sub>2</sub> initially being qualitatively reduced to NO for the measurement of NO<sub>x</sub> (NO<sub>2</sub> is the difference between measured values of NO<sub>x</sub> and NO). This use of identical sampling eliminates false negative values of the NO<sub>x</sub> signal. The PW 9762 makes use of the chemiluminescence principle which creates a reaction between NO and O<sub>3</sub> and, by providing an in-built ozone generator, the Philips analyser obviates the need for an external supply of gas—such as, for example, oxygen. Highly-sensitive pulse-counting techniques enable the analyser to be used in normal atmospheric-pressure conditions, thereby overcoming one of the earlier drawbacks of the chemiluminescence principle which demanded near-vacuum working conditions. The PW 9762 is extremely compact and fits into a standard 19-inch racking system. It incorporates its own sample pump and power-supply unit and can be ready for use within 20 min of connecting up.

Circle No. 53 on Reader Enquiry Card

**Anaerobic work centre.** Forma. Forma Scientific introduce a completely self-contained anaerobic work centre designed to add immediate anaerobic capabilities to clinical and research labs of all sizes. The work centre consists of a large-capacity glove cabinet with a highly visible work area; a built-in incubator with solid-state temperature control and a forced-draft air flow system to maintain a comfortable working environment; and a front access auto-sequence interchange with single, push-button aerobic to anaerobic conditioning for quick-in, quick-out transfer of anaerobic cultures and apparatus. The work centre is complete with regenerative palladium catalyst and dessicant dryer modules, de-ox indicators, disposable work pads, and a waste removal system. Accessories available include an anaerobic collection/transfer cart, add-on work modules, inventory racks, and a mobile instrumentation bench for set-up of an integrated anaerobic station, including a low noise, oilless vacuum pump, built-in CO<sub>2</sub> and N<sub>2</sub> gas bottle platform, undercounter storage cabinets, and dual-wheel casters for easy moving.

**On-line chemical analyser.** Kevex. The Kevex material analyser is intended for rapid and non-destructive on-line measurement of chemical compounds. The analyser includes a pre-programmed microprocessor capable of calculating the concentrations of up to 19 different elements simultaneously in as little as 5–10 s. Applications include routine quality control of fluids and slurries by batch sampling tests or continuous on-line flow analyses with the option of closed-loop control. Provisions for data logging and external signals for initiating element concentration correction or product rejection are included. The system can be fully automated.

Circle No. 55 on Reader Enquiry Card

Kevex material analyser

**Low-temperature temperature controllers.** Neslab. Exatrol and Cryotrol controllers are designed primarily to extend the usefulness of the Neslab immersion coolers by providing the ability to maintain constant temperatures at any point up from the lowest point attainable. Neslab CryoCool and Bath Cooler immersion coolers can now be operated to maintain constant temperatures from as low as -100 °C. The Exatrol temperature controller offers temperature stability of better than ±0.05 °C when used with a Neslab CryoCool or Bath Cooler. Linear cooling or heating rates can be programmed by adding the ETP-3 electronic temperature programmer. The Cryotrol model provides temperature stability of ±0.5 °C. This economical method can be used where less critical temperature control is needed. A constant low temperature bath, as well as programmed freezing rates, is now possible with this new series of temperature controllers.

## Mr Desai takes on the scientists

USER departments, more relevant research, national needs . . . familiar words in Britain during the period of the Rothschild reorganisation, familiar words more recently in Australia during attempts to dismember the the Commonwealth Scientific and Industrial Research Organisation (CSIRO). Now the Indian government of Mr Morarji Desai is going through a similar operation with its own large scientific body, the Council of Scientific and Industrial Research (CSIR). And the opposition to these moves from the Indian scientific community is extremely vocal.

CSIR is an organisation very largely conducting applied research. First established in 1942, it is most closely associated with Mr Nehru who put it on its present firm footing in 1952 and ensured, by making the prime minister its president, that the organisation had a substantial degree of autonomy, in that its director general could by-pass ministerial bureaucracy. Furthermore, Nehru made himself minister for science, and in recent years Mrs Gandhi has also held that post, so there have been the clearest signs to Indian scientists of the importance that the government attached to science and technology. In these past thirty-five years CSIR has blossomed into an organisation with forty-four laboratories including ten cooperative research associations.

The days are gone, however, when applied scientists could claim total freedom from direction. And the arrival on the scene of governments like those of Edward Heath, Malcolm Fraser and now Morarji Desai to find large expensive autonomous organisations nominally completely decoupled from departments working in the same field was bound to trigger off some very serious questioning. In cold logic many of CSIR's laboratories could as sensibly be constituent of ministries such as industry, energy, electronics and agriculture. Thus the dismemberment of CSIR with up to 28 laboratories detached to user-ministries is not without a rational basis.

Against this, however, some very serious arguments must be ranged. First, there seems to have been no consultation of scientists within CSIR before the cabinet made its decision—and thus no opportunity for the

sort of debate which might well have thrown up alternative structures. Second, CSIR laboratories are at present expected to be accessible to government and industry alike, whereas once in the control of a ministry access might become much more restricted for those not within a tight circle. This is an interesting point which in the British context would certainly be worth studying. Third, ministers with tame scientists may be tempted to use these scientists simply to bolster up their own prejudices and not for objective assessment. Fourth, India leads the world in ministerial bureaucracy and red-tape (thanks to the British), so any move that puts scientists under the control of so many paper-shufflers and rule-book-followers has to be regarded with alarm.

These are weighty objections which in the British situation were only alleviated by the placing of chief scientists of intellectual distinction right in the midst of the relevant ministries. In India, the path to new machinery may well be different but for certain it must take note of the concerns of scientists. This has not yet happened, and the government will find itself with a very dispirited bunch of scientists if it does not bring them more into the discussion.

A rather different objection comes from those who fear that the dismantling of CSIR is one stage in the process of reducing India's aspirations to technological self-reliance. CSIR has pursued many scientific projects specially aimed at cutting down the need for expensive imports, and anything that rewards the organisation for this by splitting it up is bound to be viewed with great suspicion. The Indian National Science Academy says this is an elliptical way in a statement which recognises the benefits of some foreign technology but points to the immense pools of talent available. The press have taken it up more stridently in statements such as 'CSIR has been an eyesore to the multi-nationals', and 'CSIR is the first martyr to the Janata Government's ill-concealed solicitude for the international giants'.

All this adds up to a compelling case that the government should come out and debate its proposals openly. Once CSIR is in pieces a major national asset is never likely to be put together again. □

# Science versus safety: who should judge the balance?

*R. N. P. Sutton, of the Department of Virology, Wittington Hospital, Manchester, offers some reflections on the possible implications of increasingly stringent health and safety requirements for scientific research in Britain*

EMMA LIVRY was a young and talented dancer in the Paris of the 1860s. She chose to ignore the management in a question of non-flammable material and, in consequence, was fatally burned during a performance at the Opéra. Mlle Livry weighed art against safety and paid the price.

I doubt whether such a conscious choice could be made today. Over the years, safety regulations have proliferated, culminating, as far as Britain is concerned, in the Health and Safety at Work Act of 1974. These regulations have mandatory force and, whether *post hoc* or *propter hoc*, we now have a universal obsession with safety. Living and working in a scientific community, do we expect too much when we hope that a fair balance can be struck between a crippling devotion to safety-first on the one side and a disastrous *laissez-faire* on the other? For the moment, let us confine ourselves to microbiology, for that is the field with which I am familiar.

Do laboratory workers handle pathogenic organisms carelessly? I hardly think so. In the diagnostic field, all are well aware of the dangers of hepatitis, tuberculosis and so on, probably more so than our colleagues in other disciplines. There has been much thought about the newer hazards, Lassa fever, Marburg and rabies viruses, and the risks in handling these agents are now well recognised. Special control measures to prevent the spread of infection by these and similar agents have been set up in Britain. The Dangerous Pathogens Advisory Group (DPAG), a body broadly analogous to the Genetic Manipulation Advisory Group (GMAG), has laid down procedures for the handling of these Category A pathogens. The procedures apply to laboratories which, as a matter of deliberate policy, hold or handle or might in future hold or handle these pathogens.

In laboratories with diagnostic responsibilities there are unavoidable risks in the handling of specimens. Where large areas, maybe including major seaports or international airports, are served, the chances increase of fortuitous encounter with dangerous pathogens. Facilities are required for safe handling of specimens from patients—and, indeed, the safe handling of the patients themselves—in whom exotic infections such as Lassa fever are suspected. At this stage, the practicalities of administration and finance become paramount. The necessity of expensive preparation for a rare event does not appeal to cost-effective administrators, hard-pressed by other and urgent appeals. There is a temptation to purchase a facade of equipment and, perhaps, to designate an empty room as a high security area. Justice, but not full justice, is seen to be done. In circumstances such as these, limited by unavoidable financial constraints, clinicians, nursing staff and laboratory workers may be edged into positions which are unacceptably dangerous.

But is not all this within the domain of the Health and Safety at Work Act? Here, it is expressly laid down as a duty that the exposure of persons to risks to their health and safety is forbidden. Yes, but . . . presumably, the legislators did not intend this Act to be read as forbidding nurses to dress infected wounds, laboratory workers to test

infected specimens or doctors to attend to patients with contagious diseases.

Yet dangers exist and there would seem to be practical and financial difficulties in implementing the provision of safe conditions of work, in particular with respect to the rare, but real, hazards presented by Lassa fever and the like to the ordinary hospital and laboratory of any size. Implementation of the spirit of this law is much easier when we consider the planned investigation of known infectious agents. Here, we are often on different ground, and a fable comes to mind.

In a far away land, there was a tragic disease, well known to medical men. Rumours claimed that this disease could be transmitted to monkeys and two doctors decided to try the experiment. One told his colleagues about the exciting prospects of his investigation; these friends banded themselves into a committee and prudently forbade him to handle such a dangerous pathogen. The second doctor kept his counsel and success came his way.

I am not sure whether this fable could be held to apply to any known disease. Told twenty-five or thirty years ago, it might have applied to poliomyelitis: told today, to Creutzfeldt-Jakob disease. Times change, and it is interesting to speculate on what would have happened if the early work on poliovirus had been carried out in today's climate. Would we now have a poliovirus vaccine or would the experiments have been terminated, for the safety of the laboratory workers? Either way, patients with poliomyelitis would still have been cared for and pathological specimens subjected to routine examination without much regard for the letter of any safety legislature.

In the past, experimental risks were assessed by the scientist concerned. Accepted as being in possession of the facts, and capable of marshalling them with responsibility, his decisions were given due weight. Today this is not so and we have a society where everyone questions authority and claims the right to speak and act, often on topics beyond their competence.

In this way, bodies often effectively lay in composition can inhibit individual workers through decisions which are arrived at by processes which are essentially non-scientific (risk avoidance, responsibility spreading and undue reliance upon public opinion). Such decisions, although they may well implement legislation such as the Health and Safety Act, may equally well not be in the public interest (that is "Doing today those things that men of intelligence and goodwill would wish, five or ten years hence, had been done"—Edmund Burke).

How can we strike a fair balance between the demands of safety and those of the public interest? My concern is by no means theoretical and I know personally of recent instances where local bodies, acting in their own wisdom, have attempted, in the name of safety, to ban certain microbiological experiments. On both occasions, as it happened, the offending agents were slow viruses or possible slow viruses. Next year, perhaps, influenza virus vaccines will take over the role of bogeys for the timorous in the local safety committees—who knows?

A solution may lie in changing slightly the role of the DPAG. In the few programmes involving genetic engineering, control is rightly in the hands of the GMAG. In the many experiments involving micro-organisms, the ultimate sanction in questions of safety and the power of veto should be, not in the hands of local bodies, but in those of the DPAG. In this way both the public safety and the freedom of the investigator would be protected. □

# Health and safety 3 years on

Alastair Hay traces the teething trouble of the UK Health and Safety Commission since its inception in 1974

WHEN the UK Health and Safety at Work Act (HSW Act) received the Royal Assent on 31 July 1974, a single agency—the Health and Safety Commission (HSC)—was brought into being. It was charged with securing the health, safety and welfare of people at work, and of the public out of work. The Commission has a Health and Safety Executive (HSE) to implement its decisions and coordinate the safety work previously carried out by separate agencies dealing with occupational safety and health, explosives, nuclear installations, factories and employment medical advisory services. Three other agencies were also allocated to the HSC and, in spite of considerable pressure to return them to their former status, have been retained by the Commission. They are the inspectorates for mines and quarries, farm safety, alkali and clean air.

The HSW Act states that the Commission shall consist of a chairman and "not less than six nor more than nine other members" to be appointed by the Secretary of State for Employment. At the moment the Commission has eight other members. Employers' organisations in the form of the Confederation of British Industry (CBI) appointed three, the Trades Union Congress (TUC) nominated a further three, local authority organisations two more. Although several nominations have been considered for the ninth post no single nominee has proved acceptable to both employer and employee representatives on the Commission. CBI nominees have been vetoed by the TUC representatives and vice versa. According to one member of the HSC this political infighting was only to be expected in the creation of a new organisation. It had in no way affected the work of the Commission which, he said, was "going well".

Evidence that both sides of industry are cooperating well on safety issues is provided by the safety representatives' legislation due to come into force on 1 October 1978. This provides for trades unions to establish 'safety watchdogs' in work places throughout the UK; 150,000 'watchdogs' are likely to be appointed, according to HSC estimates. When the measure was first proposed, CBI representatives opposed it, fearing that it would increase the power of trade unions; but, with no machinery other than the unions for negotiating with workers in industry, their opposition was short lived.

A further threat to the legislation was posed by expenditure cuts implemented by the government. In fact the cuts would have stopped the legislation had the CBI and TUC not put pressure on the government to secure the measure. By this time both organisations were agreed that the legislation was important. As the coal mining industry has had safety representatives at the work place for many years, the pressure is not entirely new. But its success in the coal industry is undoubtedly one reason for the HSC introducing it into others. It is also, say the HSC, the only way of ensuring that people can participate actively in decisions affecting their own safety.

## Placing responsibility

The 1974 Act is quite explicit when it places responsibility for safety at work; it is the duty of every employer to ensure, "as far as is practicable", that his employees are not "exposed to risks to their health and safety". The HSE's factory inspectors have the task of ensuring that the law is enforced in the factories of manufacturing industry in the UK. In the past these inspectors had to be generalists, each one being responsible for about 500 different premises. Today there is a different strategy: inspectors concentrate on specific problem areas. A new class of specialist inspectors is being trained who will be better able to advise local safety representatives.

These inspectors are well armed too. If any employer does not comply with an 'improvement order' an inspector can issue a 'prohibition order' to stop a particular activity. In the HSC's report for 1974-76, inspectors are reported to have served 5,433 improvement notices, 1,951 immediate, and 799 deferred prohibition notices. Of the 44 appeals lodged against these notices, 31 were withdrawn, some were modified but in no case was a notice cancelled. In the HSC's view this outcome is "very satisfactory"; the Commission's inspectors are using their legal powers, but with prudence.

Prohibition notices are unlikely, however, to be served on the directors of research laboratories in the UK. According to Audrey Pittom, the Director of the Hazardous Substances Division of the HSE, "enforcement or spot checks are not necessary for research institutions". In Miss Pittom's view, scientists obviously need to exercise care in the laboratory. But she ac-

VCM worker with personal monitor

knowledges that most scientists are usually well versed in the hazards involved in their work. She says that the HSE feel that it is the large scale production processes in industry that present the real dangers. It is in these circumstances, where there is a long chain of command with no single individual responsible for the whole operation, that problems arise; this, she adds, is not the situation in the laboratory.

In laboratories where the staff are organised in trade unions, safety representatives with legal powers will be appointed by October 1978. Many well run laboratories already have safety officers so this measure is unlikely to bring about any serious disruption. It will probably be those laboratories engaged in work of a multidisciplinary nature where scientists, adequately trained in one field, can venture into another, which will come under closer scrutiny. This is an area of concern for many laboratory safety officers who argue that the technicians employed in these laboratories are often unaware of the dangers they run, either because they have not been told or simply because their employer's don't know the hazards themselves.

## Genetic engineering

One of the HSC's proposals has been viewed as a serious provocation by sections of the scientific community. It concerns the Commission's all embracing definition of what should, or should not, pass for genetic engineering. The Commission feels that there must be regulations to cover this useful, but potentially dangerous research field. Its guidelines, put forward in a discussion document last year, were deliberately all-encompassing: in the words of a spokesman for the HSC it "did not want to leave anything out". The definition certainly did not do that. In fact one commentator remarked

ironically that the definition was so broad that it would even preclude consumption of a bowl of yoghurt.

But this was not the only response from scientists to these proposals. Reaction was often far more extreme. Some biologists attacked the recommendations with a fervour bordering on hysteria, principally, says the Commission, because they were not fully informed of the reasoning behind the proposals. The Commission feels that some over-reacted, others were initially slightly misguided, but that the majority discussed the recommendations rationally. Note has been taken of these discussions and the Commission is now proposing a more selective definition of genetic engineering. It has yet to be approved by the Secretary of State for Employment.

On the subject of industrial carcinogens, the HSC view is unequivocal; industry must take more effective measures to reduce the risks. Inspectors in the HSE point out that workers in specific industries are still developing cancer. More and better surveillance is necessary. The HSC uses as its guidelines the recommendations of the 59th sessions of the International Labour Conference on the prevention and control of occupational hazards from carcinogens.

As a first step to limiting the spread of carcinogens, the HSC is preparing a notification scheme for all new substances. Where the quantity manufactured in, or imported into the UK exceeds 1 tonne per year, advance information on the substance's toxicological properties must be sent to the HSC. Substances already in use before the introduction of the scheme are exempt from its provisions unless there is evidence that they present a particular hazard.

Included in the toxicological details will be information about potential carcinogenic properties. As industry will be required to do its own testing, this will have to be done according to a protocol agreed with the Commission. Animal studies are still regarded by the HSC as the most effective for determining carcinogenic potential. But as they are expensive, the Commission argues that they are not feasible as screening tests for large numbers of new substances; the short term tests now available are more practical. Two short term tests favoured by the Commission are the Ames test—for assessing mutagenic properties in bacteria—and *in vitro* cell transformation in cultured cells. It is the Commission's view that the results of these tests, as well as other factors such as chemical structure, nature of exposure and the number of workers exposed, should be considered in assessing whether addi-

tional tests are necessary. Some scientists point out that co-carcinogens are not covered by short term tests, and they add that some attention must be devoted to this problem.

The Commission is unlikely to ban substances, however, simply because they are carcinogenic. The activity of the carcinogen, its use in industry and its manufacturing process will be considered before resorting to a banning order. The Commission feels that cleaner manufacturing techniques could reduce the risk to workers from some carcinogens. Audrey Pittom cites the case of vinyl chloride monomer (VCM) as a substance, which can be "control(led) without prohibiting". VCM, an important polymer in industry but linked with the deaths from angiosarcomas of a former ICI employee and a worker at British Petroleum, is now subject to far stricter manufacturing procedures than existed in the past. Thus vinyl chloride, once even mooted as a potential anaesthetic, has escaped the prohibition notices served on some chemicals in the UK, such as  $\beta$ -naphthylamine and benzidine.

In the final analysis it is epidemiological evidence which is necessary for assessing the carcinogenic risk a substance carries for humans. To assist with this, the HSE, and TUC in particular, would like to see industry keep better general medical records of employees. A few specific industries do keep this information but the TUC feels that all industrial concerns should do likewise. Some argue, therefore, that it is almost certain that pressure will be exerted on the government in a year or two to introduce amending legislation to the HSW Act to secure this end.

#### Unlikely measure

A measure not likely to be adopted in the UK in the fight against carcinogens is the proposition put forward by doctors representing two German chemi-

cal giants—Hoechst of Frankfurt and Bayer of Leverkusen. The doctors suggested that older workers be employed in plants manufacturing dangerous chemicals on the basis that a more experienced workforce exercised more care in handling toxic substances, and that if there was a latency period of 20–30 years between first exposure and the development of cancer, these workers may be less at risk of developing cancer than their younger colleagues.

The companies made it plain that they had never adopted this practice themselves and a spokesman for Hoechst said that it might be possible to implement the decision in smaller factories, but not in one as large as his. Reaction to the proposal in Germany from the Ministry of Labour, members of parliament and trade unionists was understandably hostile; it is hardly likely to be adopted. In Britain, Mr Bill Macmillan of the Chemical Industries Association thought that the proposal was an "interesting approach" but he insisted that it was "not one we apply in Britain, nor is it one which as far as I am aware had ever been considered in this country". Spokesmen for both the HSE and one of the larger chemical unions in Britain said that the suggestion was "politically unacceptable". The real flaw in the Hoechst suggestion as far as the HSE spokesman was concerned, was that if there was a risk of someone being exposed to a carcinogen it would be impossible to restrict the substance merely to the factory confines and prevent other people in the environment being exposed.

Thus the HSC and its Executive have to look at safety measures from both a political and technical standpoint. The Commission has had to exert some political muscle to resist pressure from mining and agricultural interests to have their safety inspectors detached

Heat exchangers at VCM plant

from the HSC and reinstated in their former guises. Attempts to have the Alkali and Clean Air Inspectorate returned to the Department of the Environment have also met with little success. But this should come as no surprise, for few governments would wish to see their own creations dismembered so early in life, and the HSC

is after all a protégé of a Labour government, albeit its second term in office.

It remains to be seen whether future British governments take the demands for dismemberment more seriously. By that time, however, most of the arguments in favour of such a measure will no longer apply, for the various in-

spectorates will be more coordinated, and existing and proposed legislation will be more in tune. As for the 1974 HSW Act, the results of that legislation can only be judged some years from now. Many are in no doubt that the Act will be shown to have achieved its objective, that is, a safer working environment in the UK. □

## Protecting production or workers?

In November 1974, the British Society for Social Responsibility in Science reported in *Nature* on its work on vinyl chloride monomer. The Work Hazards Group of BSSRS sent *Nature* this update of its activities:

OVER the past three years, BSSRS has expanded its hazards programme with the aim of providing information to those directly at risk on the factory floor and to community groups directly affected by industrial hazards. We now publish *Hazards Bulletin* five times yearly which includes material on particular hazards, developments in health and safety legislation, legal cases and trade union struggles for health and safety in the workplace. Pamphlets on noise, oil, vibration and asbestos dust provide more comprehensive analyses of the effects of these hazards and how to fight them. Our hazards enquiry service now receives 50-75 enquiries per month. Local hazards groups work within trades councils, local trade union branches and community groups on health and safety issues, and we talk directly to safety representatives and shop stewards on day release safety training courses organised by concerned members of the trade union movement. This direct contact has been invaluable to our work.

While we have been developing our work at the rank and file level, worldwide concern about environmental hazards has increased. The enormity and horror of the disasters at Flixborough and Seveso, the struggle of the inhabitant of Minimata Bay to obtain compensation for the damage done by mercury poisoning, the poisoning of the state of Michigan by PBB, the militant demonstrations against fission reactors in France, West Germany and the United States, have all forced the scientific communities in industry and the universities to begin a more systematic evaluation of the hazards of old and new technologies. So far, unfortunately, this response has been grossly inadequate, reflecting a remoteness from the problem and a lack of fundamental concern for those who are directly at risk.

A conference on risk held at Imperial College, London, last May and organised by the Council for Science and Society (CSS) and the ensuing leaders and articles in *Nature* (19 May, 26 May) expressed fundamental differences of approach between our work and current academic and industrial considerations. The dominant note struck at the CSS conference and echoed in the pages of *Nature* is the need to guarantee production. Health and safety issues are secondary to the needs of maintaining and increasing production. While this approach is understandable from the point of view of those responsible for planning the economy it is unacceptable

to those directly at risk in the factories and the neighbouring communities. Significantly, trade unionists and community groups are virtually excluded from conferences such as the one organised by CSS where the issues are discussed and where policy begins to be formulated.

Aside from the inexcusable absence of those directly affected by the discussions and the decision making, there are fundamental problems when the emphasis is on guaranteeing production first and safety second. Such protection as is provided involves enclosing the worker in cheap protective clothing rather than enclosing or redesigning the production process itself. Industry sees the problem as protecting the operation and design of the process, an attitude which characterises a number of industrial approaches to health and safety.

The first approach is a reluctance to accept that a hazard exists. The asbestos industry still claims that there is no risk to the general public from asbestos (remarks of Alex A. Cross, chairman, standing committee, International Asbestos Information Conference at Asbestos Information Association Third Annual Industry-Government Conference, September 8-9, 1976). The second approach is to accept that a hazard does exist but that it is small. This leads to the notion of acceptable risk and threshold limit values (*Hazards Bulletin* 7, July 1977) in an effort to quantify the argument. In the case of asbestos, standards are set at 2 fibres per cc, which is a factor of ten greater than that demanded by the trade unions representing the majority of workers exposed to asbestos. Our evaluation of the literature leads us to give unqualified support to this very minimal trade union demand and we have urged trade unions to ban asbestos and get it replaced with the numerous safer alternatives that are commercially available (*The Asbestos Hazard*, Birmingham Hazards Group, 67 Woodstock Road, Birmingham 13).

A third argument employed when faced with an apparent contradiction between production and safety is to compare the risk with other already existing dangers. The use of fatal accident frequency rates (FAFR) frames this approach. According to FAFR statistics, which ignore occupational disease, non-fatal crippling accidents, the effects of shift work and other debilitating hazards, mining is less hazardous than driving a car. Such an argument paints a picture of the public as being irrational in opposing one hazard while seeming to accept another without protest. The *Nature* leader (19 May) supports this argument without recognising that there is no mechanism for car drivers to affect their hazard directly. The sensation

generated by Ralph Nader's book, *Unsafe at Any Speed*, shows how much interest there is in automobile safety and at the same time how difficult it is to mount a campaign for it. The crucial difference between these 'widely accepted' hazards and hazards at work is that people at work have the organisation, numbers, and power to effect change. The use of this inappropriate comparison serves to blunt the force of the basic demand for adequate health and safety precautionary measures. It is shocking to realise that for the vast majority of fatal accidents at work the hazard is recognised and the safeguards are known (*Accidents in Factories*, HMSO 1971).

The fourth and most critical argument is the claim that adequate protection is simply too costly. Mr Jack Sheppard, managing director of Turner and Newhall, one of the biggest asbestos fibre processing companies in the world, testified at the Government Advisory Committee on Asbestos that the TUC demand of 0.2 fibres per cc would close the UK asbestos industry entirely. The forced choice between jobs and the environment has been one of the most effective methods of getting people to accept unsafe living and working conditions. This can only be fought effectively by supporting the health and safety struggles in other countries and trying to prevent the export of hazardous operations to countries with less stringent requirements.

The BSSRS Work Hazards Group disagrees completely with the management approach of protecting the process. First, not only do we ask if it is safe; we ask, who is it safe for? Present industrial safety considerations are confined at best to the general public and express little concern for the workforce itself. Second, we ask, who pays for the cost of safety? If government or industry decides not to pay, this does not mean that the cost vanishes. Far from it. The individual affected pays the cost in poor health, lost wages and early death. This is a shifting of cost, not the saving of money. In the Robas Report, accidents were estimated to cost the nation 0.8% of the GNP. Third, in our practical work with trade unions we support the view that no matter how much information they may have, there is still a fundamental difference in perspective between the worker on the shop floor and the requirements of management.

It is this conflict between those who control production and those who need safety, between those who assign the risks and those who are exposed to them that must be acknowledged. There is a continuing need for scientists and technologists who are prepared to acknowledge this conflict to help make available to working people the information they need to ensure their health and safety.

## EUROPE

# Harmony of practice

*The European Science Foundation's general assembly heard of progress last week in controlling genetic manipulation experiments. Chris Sherwell reports from Strasbourg*

EUROPEAN initiatives in controlling recombinant DNA research will continue in spite of the hiatus reached in the United States, where no legislation now seems likely in the coming year. The pace set by the USA hitherto has slowed considerably in recent weeks with evidence that the dangers are less than at first expected, and the bill introduced by Senator Kennedy has now been withdrawn.

European efforts, however, though largely focused on the subject of legislation, are not directed at producing harmonisation of individual countries' guidelines. The chances of doing this are now widely regarded as negligible, more because of the work each country has put into creating guidelines suited to its own circumstances than because scientists have differed in their estimates of what are conjectural risks. Moreover, in practice the decisions of the European countries' equivalent to GMAG (Britain's Genetic Manipulation Advisory Group) have proved to be very similar across a broad range of experiments.

The aim now is therefore directed at harmonisation of practice in the individual countries. The intention is that individual representatives of national genetic manipulation advisory groups should supply lists of sanctioned experiments together with the relevant containment conditions. Anomalies would be discussed, and countries out of line would be expected at least to reconsider their position. Harmonisation would thus consist in concurring at regular meetings on decisions already taken.

The meetings, which should now take place every six months, are of the liaison committee for recombinant DNA research of the European Science Foundation (ESF). This met for the first time on 15 March this year, and again on 19–20 September. As a result of the first meeting, at which various countries' practices were surveyed, a small group of legal experts and scientific advisers met on 22 June to discuss common elements for possible controlling legislation. It considered licensing of facilities, consultation and compliance with controlling bodies, and an issue which had tormented the liaison committee meeting,

that of patents.

According to the ESF annual report agreed in Strasbourg last week, the September meeting supported the legal committee's finding that researchers' interests would be best protected if national committees requested information necessary only to assess suitable safety precautions. That the subject of legal safeguards and patents is a potential problem is revealed by the British case. Here, GMAG's dual role as both a technical advisory committee and as a watchdog for the public interest has made winning the confidence of industrialists, for whom the patents question is highly relevant, especially difficult.

Elsewhere the conflict of interest implicit in this dual role is resolved by creating a small technical advisory committee which looks at individual cases in detail and then delivers suitably edited reports to the full committee. It is a solution adopted on the European level as well: the ESF liaison committee's technical advice comes from EMBO's standing advisory committee on recombinant DNA research, which consists solely of molecular biologists.

The September liaison committee meeting also agreed on certain general points—that any effective legislation should provide for notification to some responsible body, and for licensing and inspection of facilities by that body. The idea that individual projects should receive prior approval was not unanimously endorsed, but the keeping of records and the idea of legislative review did receive support.

The liaison committee also considered technical safety issues which were the basis of a questionnaire distributed on the subject following a separate and informal meeting in June. The assistance of the EMBO committee will be sought on discrepancies between decisions of national safety committees and the revised NIH guidelines. Other areas of interest include the lowering of safety measures where the DNA to be cloned is pure, the criteria of pathogenicity for purified recombinant DNA molecules, the principles and application of biological containment, and the safety measures needed for recombinant DNA research using plant and animal viruses.

Out of all this a pan-European code may or may not emerge. For the moment, the objective is practical. And it has the useful purpose of serving the mutual interests of recombinant DNA researchers and of the European Science Foundation. □

## Europe's danger

A WARNING about the future of science in Europe is contained in the annual report of the European Science Foundation (ESF), endorsed last week in Strasbourg at its third general assembly. But while the threat has not been spelled out quite so cogently before by an international scientific body, the ESF announced no comprehensive plan to help counter the danger.

The problem, a product of the mid-1970s, was summed up by Sir Brian Flowers, re-elected to the ESF presidency for another three years. If the trend of dwindling support for the important innovative research done by Europe's small scientific groups continued for too long, he told a press conference, the progress of science would be affected at the point of origin. But he confessed: "This subject was not discussed very much". He added only that it was "accepted by everybody present".

Sir Brian went on to list the assembly's achievements. Apart from moves in the field of recombinant DNA (see accompanying story), these included the establishment of a committee to conduct a feasibility study on a synchrotron radiation facility, progress of an ad hoc group on taxonomy in the fields of zoology and botany, and an elevation in the status of ESF committees on the social sciences and the humanities.

Some concern was voiced privately last week at the number of ESF committees: delegates saw a need for more tangible action. At present there is only the European Training Programme for Brain and Behaviour Research, which awards grants for travel and training, and financial support for the mathematics and physics research programme of the Institut des Hautes Etudes Scientifiques. Nor did the ESF make any statement of its position on the issue of human rights.

The ad hoc group to study the design, costs and site of a European synchrotron radiation facility will be headed by Professor Hagedoorn of the Netherlands. Its predecessor, under Professor Maier-Leibnitz, found that research using such radiation sources, which is parasitic on high energy physics facilities, had reached a stage where the lack of control undermined progress. The hope is that work will start on a European facility in 1980, to be ready by 1985. This will be in addition to such other European projects as CERN, ILL, EMBL, EISCAT, JET and the European observatories.

The decisions concerning the social sciences and the humanities add two standing committees (the former to be chaired by Jean-Jaques Salomon) to the two in existence, which embrace the science research councils (ESRC) and the medical research councils (EMRC). But the idea of helping post-doctoral students in these two areas through fellowships and workshops—which in expanded and broadened form would obviously help counter the danger to science described in the ESF report—met an obstacle over how any such scheme would be financed. It proved to be the only spark of controversy at an otherwise routine gathering.

Chris Sherwell

## GERMANY

## Stagnation in industry?

*Werner Gries report from Bonn about statistics on research in Germany today*

ACCORDING to a review presented by the federal government to the German parliament, research expenditure in the federal republic amounted to DM25,960 million in 1976, 2.3% of the gross national product. The total number of staff employed in R&D, some 303,500, has been stagnating for three years; the number of persons employed in research in the industrial sector has actually declined. Expenditure for 1977 is estimated at DM27,300 million, up 5.3% on 1976.

The government's share of total research expenditure in Germany is about 51%, industry's share about 48%. Some 60% of research expenditure is effected through government grants in the industrial sector, where the state pays an average allowance of 20% of industry's own expenditure. This support amounted to DM3,000 million in 1976, of which DM1,200 million went to defence R&D and the rest to civilian R&D. Of government expenditure on civilian R&D, 72% is handled through the federal Ministry of Research and Technology.

In 1975, the latest year for which figures are available, 186,200 persons were employed in R&D in industry. This represents a decline of 6.5% compared with the peak in 1971 of 200,000 employees, but the decrease was in the number of assistant staff and not of research workers themselves. The number of research workers rose by 8.8% over 1971-1975, and assistant staffs were considerably reduced. The decisive factor may have been the pressure of costs in the German economy. As possessors of technical knowledge, research workers were not dismissed, while the work of the assistants was increasingly done by highly trained research workers.

Industry's research expenditure is concentrated in a few firms, as evidenced by the fact that 96% of research expenditure is effected by firms which have more than a thousand employees. Government promotion of research in industry has also concentrated on those firms which have the largest research budgets. Only 6.3% of government research funds in recent years have been for the benefit of small and medium-sized firms. The promotion of research by fiscal means is at present of only minor importance in the industrial sector, because several tax concessions for research were stopped in 1975. The

proportion of funds accruing to firms via fiscal promotion of research is about 2% of the total research expenditure financed by the firms themselves.

The distribution of research expenditure among the branches of German industry bears examination. Steel construction, mechanical engineering and the motor vehicle industry used 34% of the total for all firms. These industries also received 48% of government research money for industry. The number of research personnel in these industries declined in the years 1971-73, however, from 62,100 to 54,300.

The electrical engineering, precision engineering and optical industries used 30% of research expenditure by firms. They received, on average, government allowances of 15% of their own expenditure. Research staffs in these industries have increased slightly in recent years, but electrical engineering experienced a decline from about 53,900 in 1971 to 52,700 in 1973.

The third largest and most research-intensive branch of industry in Germany is the chemical, oil and plastics sector. Some 28% of firms' research expenditure is done in this branch of industry, and it receives only 2% of its research expenditure from the state. Research staffs in the chemical industry fell from a peak of 50,400 in 1971 to 47,400 in 1973. The reduction was not in the number of research workers but in their assistant staffs.

Remaining branches of industry use only 7% of research expenditure by firms. But taken as a whole the figures indicate that stagnation in research expenditure has set in even in Germany. In the industrial sector there is a real decline in research expenditure and a reduction in personnel. It is a trend which can be observed in several other western industrial countries, except for Japan.

● The federal government will distribute DM436.3 million for projects in non-nuclear energy research in 1978, chiefly to build demonstration projects in coal refining, district heating and hot water supply from solar energy. Fundamental research will be supported in coal technology, energy conversion and the efficient use of energy.

Under a special economic programme, a number of prototype plants using new energy technology have been promoted, notably the use of heat pumps in public installations. The largest (4.65MW) gas heat pump in the world so far started working at Paderborn on 21 October 1977. □

## USSR

## Brezhnev's surprise

*Vera Rich reports on Mr Brezhnev's jubilee speech for the sixtieth anniversary of the October revolution*

MR BREZHNEV's jubilee speech followed traditional lines for the most part but contained two surprises. The most remarkable feature of his speech was the section on reducing the danger of nuclear war. In addition to the well-reported commitment to an eventual total ban on nuclear weapon tests—to include underground as well as atmospheric, outer-space and underwater tests—he stated that the Soviet Union was prepared to agree to a moratorium on peaceful nuclear explosions (PNE).

PNE forms an important part in the Soviet plans for diverting the Siberian rivers southward to irrigate the arid steppes of Central Asia. This diversion is not entirely dependent on PNE: for explosions below 10 megatons, conventional explosives are more cost-effective, except where difficult terrain poses special logistic problems. Nevertheless, a year ago the Soviet media began to comment extensively on the use of PNE in the project, and it was envisaged as a major mark of progress. Indeed, so anxious were the Soviet authorities to use PNE in the diversion project that they were even prepared to agree to on-site American inspection. Now, however, Mr Brezhnev is apparently willing to sacrifice the whole project as the price of a test-ban treaty, and to revert to more conventional means of canal-building.

The other major surprise was the figures for this year's harvest. In spite of fervent denials by the foreign services of Moscow radio, Western experts had expected a shortfall of some 8 million tonnes. Although Mr Brezhnev made no reference to shortfall, the total yield of 194 million tonnes means that the shortfall from the target is no less than 19 million tonnes. Although the weather must be largely held responsible, it is not surprising that the future plans for agriculture stress the intensive development of agriculture.

Other present and future plans outlined in the speech include the opening up of Siberia by the Baikal-Amur railway, the new plans for developing the non-black earth zone, and "the discovery of new sources of energy and substitutes for many types of natural resources, the technical re-equipment of the economy to reduce manual and especially arduous labour to a minimum, the boosting of agriculture, the combating of disease, and the prolongation of the human life-span". □

## IN BRIEF

**Porton decision due**

A decision on the future of the Microbiological Research Establishment at Porton is expected shortly now that the Medical Research Council has considered the complete report of its special advisory committee under Professor Sir Robert Williams and transmitted it to the Secretary of State for Education and Science. The Ministry of Defence is due to leave the establishment by 1 April next year.

The advisory committee assessed the scientific potential of Porton for civilian research. The Institute of Biology has published its written evidence in the latest *Biologist*. The institute considers that the pilot fermentation plant, enzyme laboratory and containment facilities, together with staff and ex-

pertise, should be retained, developed and exploited rather than dissipated and dispersed.

**Nuffield's good turn**

The Nuffield Foundation has decided to help UK scientific and medical research, by supporting projects which would normally receive research councils' money but which might go unfunded. It means a temporary change of policy for the Foundation, which was set up to support research leading to social benefit for which there is no ready source of public money. The Trustees have already allocated funds amounting to about £60,000 for research which they normally would not consider. The level of support is expected to increase next year.

In 1976, of the £1.67 million income (up almost 25%), £1.16 million was spent on support for research. Only £50,000 of that went on scientific research, however, and £70,000 on medical research. The latest annual report says one reason for the small demand on Foundation resources may have been that researchers assumed funds were low after the Foundation sold its shares in British Leyland.

**NASA reorganisation**

A reorganisation of NASA by its administrator, Robert Frosch, includes a revised role and title of chief scientist, who will advise on the agency's "total programme from the standpoint of scientific objectives". The change takes effect this week.

Most people think that the only way to conserve wild plants and animals is to leave them alone. They imagine that the perfect nature reserve is an area surrounded by a man-proof fence, where natural processes can proceed without his baleful influence. This is sometimes true. The immense national parks in North America, areas like the Kruger Park in South Africa, and some reserves in the less-inhabited parts of Poland and Scandinavia require the minimum management of their vegetation, though even under these favourable conditions the larger mammals may increase beyond their optimum and require control.

The situation in countries like Britain is generally very different. We have a few large nature reserves in the highlands and islands of Scotland where nature can be left to take care of itself. Here the main management is to control man, including over-zealous naturalists who wish to collect rarities, and over-enthusiastic ecologists whose scientific sampling may destroy the vegetation. But even the most 'natural' area has probably been modified by human activity, perhaps by eliminating wolves and other predators, which allow deer to increase to numbers which ruin the vegetation unless they are severely culled.

In most areas man has reduced the tree cover and so encouraged the development of moorland vegetation. The conservationists, many of whom believe they are preserving natural conditions, oppose any move by farmers to restore the fertility destroyed by the agricultural techniques of our iron age ancestors. They produced the present beautiful—but semi-desert—landscape of, for instance, Exmoor.

Nevertheless, in many parts of Britain the native vegetation may develop if it gets the chance. The famous Broadbalk Wilderness at Rothamsted Experimental Station was a wheat field until it was enclosed and

**Managing wildlife****KENNETH MELLANBY**

left alone over a hundred years ago. Soon shrubs and trees appeared, and it is now a small wood of oak, ash and other indigenous species. At Monks Wood in Huntingdonshire we started a similar experiment on a larger scale in 1960, by leaving the ten acre Stocking Close field, an area which had been arable for centuries, uncultivated. Within seven years it was covered with a scrubby growth of hawthorn and dog rose, with a scattering of oak of up to 100 saplings per acre. It was clearly on the way back to something very like the natural deciduous woodland which covered southern Britain before man

cleared it for his farms.

However, such natural regeneration may be thwarted by some of the exotic species man has introduced to Britain. When we began the Stocking Close experiment, rabbits were very scarce following the spread of myxomatosis in 1955. Today rabbits are common again, and though acorns are still scattered around the countryside by jays, pigeons and small mammals, many seedlings are destroyed. In some parts of the country the aggressive imported sycamore prevents native tree species from becoming dominant, and so management is needed to produce natural forest.

Things may be even worse in other countries, particularly in oceanic islands. In Mauritius, for instance, conservation is a nightmare. Man has been there for under 500 years, and in any numbers for 200, but he has left little of the unique indigenous flora and fauna. Though he has exterminated birds like the dodo, and removed most of the natural vegetation to grow sugar cane, it is his introductions, plants and animals, which provide the worst problems today. Where small relict areas of indigenous trees are preserved, they are swamped with the rampant growth of guava and bramble (introduced species) producing impenetrable thickets which defy control. The introduced monkeys delight in destroying the nests of the rarest birds, and mongooses in killing the most interesting mammals and reptiles. Thus conservation may provide the most difficult management problems not in developed areas where man is obviously dominant, but in an oceanic paradise where nature might be expected to control the situation.

## What is unusual?

SIR,—In Sakurai's interesting discussion of the relation between equatorial solar rotation and climatic changes (29 September, page 401), a rather unfortunate choice of terminology is used in referring to "the Earth's present unusual climatic conditions". Unusual by what standard? The best evidence of available data covering the past 1,000 years or so suggests that the period roughly from the 1920s to the 1960s was the most unusual 50-year period of the entire millennium, in climatic terms, at least for northwest Europe (H. H. Lamb, *Climate: Present Past and Future*, vol 2 (Methuen, 1977)). Studies such as that of Eddy (*Scient. Am.* **230**, 80–92, 1977) indicate that this was also an unusual period in sunspot terms, with very high peak sunspot numbers, in line with the general conclusions of Sakurai, Volland (28 September, page 400) and others.

The possibility of a return of climate towards nineteenth century conditions should not be regarded as 'unusual' climate except on the scale of a human lifetime; the unfortunate coincidence that an explosive growth of population and demand for food has happened over just that time makes it all the more important for us to develop an understanding of what really is 'normal' in climatic terms, and I would therefore urge Sakurai and other workers in this field to avoid misleading use of emotive terms such as "unusual". If the relevant sentence is rephrased to say "variation of the equatorial rotation speed may be responsible for the recent unusual climatic conditions on Earth, now returning to the normal conditions of recent centuries" the implications of the change for the activities of mankind are much more clearly apparent.

## Missions to Halley's comet

SIR,—The informative article by David Hughes (11 August, page 468) concerning the proposed fly-by and rendezvous missions to Halley's Comet was, unfortunately, less than fair to the achievements of those who have been striving to perfect various space electric propulsion techniques.

In particular, his description of ion drive and solar-sail propulsion as "... two mechanisms (that) are still at the theoretical stage ..." is certainly far from true of ion propulsion systems.

Several laboratories in the USA and in Europe have devoted many years of effort to developing ion thrusters of different kinds. The electron bombardment ionisation type, originally devised by Kaufman, has emerged as firm favourite, at least in the USA and the UK, and several versions are now ready for space qualification. These include the 10 cm diameter, 10 mN thrust T5 device developed by the Royal Aircraft Establishment, with assistance from the UKAEA Culham Laboratory and British industry, and two thrusters of 8 and 30 cm diameter, produced by Hughes Research Laboratories under a programme directed by the NASA Lewis Research Center.

The highly-efficient 30 cm thruster is particularly well-suited to cometary rendezvous missions. Its thrust of about 130 mN is appropriate to a multiple thruster, modular propulsion unit concept, with power being derived from solar arrays. This principle readily allows a wide range of throttling to match the available power as the distance of the spacecraft from the sun varies.

The application of this thruster to cometary missions has already been studied in great depth, particularly with regard to Comet Encke, and detailed designs have been produced of the necessary flight systems.

It should also be pointed out that, far from being "at the theoretical stage", two Kaufman-type ion thrusters were flown experimentally as early as 1970. They then operated successfully for 3,763 h and 2,011 h. In 1976, one was still capable of being run under its design conditions, whilst the other exhibited a single fault.

## Engineers' salaries

SIR,—In your editorial 'Room at the top—for whom?' (22 September, page 275), you quoted, from our report to the British Association Coordinating Group, some figures concerning salaries of engineers compared to other pro-

fessional groups in manufacturing industry. The inference you draw, that salaries in production industry "... discriminate against the scientist and engineer ...", is exactly what the graphs of median age/earnings profiles appear to show, but the point we wished to bring out was that this inference is not justified.

The graphs were of median and upper quartile salaries by age for all the professional staff (22,400) in a number of leading companies. Within this total, there were 7,386 engineers compared to 607 chartered accountants and only 141 lawyers, and we were careful to give the number in each professional group. Chartered accountants are trained, and in general gain their early experience, outside industry. A limited number are recruited by industry for functions which of their nature are mainly concerned with matters at or close to Board level. By contrast, as we show elsewhere in the report, the majority of graduate engineers initially go into industry, and industry also has an overwhelming stake in those who qualify via HNC/HND and institution membership. They are employed in a wide range of jobs, from basic technical work to Board level.

Therefore, if industry succeeds in its normal job evaluation objective, to pay comparable salaries for comparable jobs, small groups of professionals selectively employed by industry will show higher median or upper quartile age/earnings profiles than a large group of professionals generally employed. It is tempting to believe that upper quartile, and in particular upper decile, graphs will show a fair comparison, but unless the samples are carefully matched in each age group this is not so.

Using exactly the same salary data, we went on to look at the number in each professional group earning salaries on or above £10,000 a year. This is one way for the companies in the survey, of answering your headline question "Room at the top—for whom?". The 749 engineers enjoying these salaries represented only 10.1% of their group, but they outnumbered the accountants, lawyers, economists and arts graduates put together.

## Tubulin assembly

from L. A. Amos

THE factors controlling the assembly of tubulin into microtubules are still under intensive study, although it is now five years since Weisenberg (*Science* **177**, 1104; 1972) first found conditions in which microtubules would assemble from a brain protein extract at 37 °C and disassemble on cooling to 5 °C. Microtubule protein purified by several cycles of assembly and disassembly does not consist only of tubulin: a number of so-called microtubule-associated proteins are observed to copurify with tubulin, most of whose functions are as yet unknown.

In 1975, it was reported that tubulin purified by ion exchange chromatography would not reassemble under Weisenberg's conditions, unless at least some of the associated proteins were returned to the mixture (Weingarten, *et al. Proc. natn. Acad. Sci. U.S.A.* **72**, 1858; 1975; Murphy & Borisy *Proc. natn. Acad. Sci. U.S.A.* **72**, 2696; 1975). The accessory factors in the extract were shown to be protein and seemed to act stoichiometrically rather than catalytically in stimulating tubulin assembly. Much of the controversy since has arisen because of the considerable variation in non-tubulin components of microtubule protein purified in slightly different conditions in different laboratories. In many cases, the most prominent components appear on SDS polyacrylamide gels as a small group of bands corresponding to unusually high molecular weights (of the order of 300,000 daltons) which have been called HMW (Borisy *et al. Fedn. Proc.* **33**, 167; 1974). Other less prominent bands are observed between 55,000 and 80,000 daltons. Borisy *et al.* found HMW in stoichiometric amounts in their preparations, corresponding to one HMW molecule per 10–15 tubulin dimers, but much lower proportions of HMW to tubulin have been reported. The positions and intensities of the other non-tubulin bands seem also to vary. In preparations from Kirschner's laboratory, HMW is found only as a minor component. He therefore suggested that the assembly-stimulating

factor, which he named 'tau' was one of the lower molecular weight proteins.

Recent papers by Murphy *et al.* (*Biochemistry* **16**, 2598; 1977) and Cleveland *et al.* (*J. molec. biol.* **116**, 207; 1977) both describe the fractionation of the associated proteins into HMW and tau components. Although the two groups used quite different methods of chromatography to effect the separation, the results are in good agreement. Both found the activity present in both major fractions. Murphy *et al.* ascribe 60% of the activity to HMW and 40% to the tau fraction. Cleveland *et al.* found a third of the original activity in their tau fraction, the remainder presumably being in the HMW fraction, which in their preparations also included some very low molecular weight material.

Cleveland *et al.* have gone on to purify further the active proteins in the tau fraction and have identified a family of four polypeptides with molecular weights between 55,000 and 62,000 which they name tau I–IV. In an accompanying paper (*J. molec. Biol.* **116**, 227; 1977) these proteins are characterised in some detail and are shown to have some interesting properties, including the ability to retain their activity after being heated to 75 °C for 1 h. By comparison, the activity in the HMW fraction is much less stable. Although the tau molecules seem to be highly extended, the amino acid compositions (including relatively high proportions of glycine and proline) and circular dichroism measurements suggest a low content (12%) of  $\alpha$ -helix. Finally, their overall charge is neutral or only slightly basic.

The latter property is rather surprising in view of the assembly facilitating activity shown by various unrelated polycationic substances, such as poly-L-lysine, DEAE dextran and RNase A (see Erickson & Voter *Proc. natn. Acad. Sci. U.S.A.* **73**, 2813; 1976), although the polymers formed in such cases are not usually normal microtubules. It has also been shown recently (Herzog & Weber *Proc. natn. Acad. Sci. U.S.A.* **74**, 1860; 1977) that pure tubulin can be induced to assemble into microtubules simply by the addi-

tion of 10 mM MgCl<sub>2</sub> to Weisenberg's buffer. However the critical tubulin concentration is 10 times as high (2.5 mg ml<sup>-1</sup>) as in the presence of associated proteins and the resulting microtubules are considerably less stable. As Cleveland *et al.* point out, the role of the accessory proteins in assembly seems to be to shift the equilibrium for an interaction which is unfavourable under normal conditions. The manner in which this is achieved does not seem to be simply a matter of counterbalancing charges on the tubulin molecules.

The possible relationship between tau and HMW is likely to be debated for some time. When it was discovered that HMW is readily proteolysed, even during storage of the purified protein, Sloboda *et al.* (*Biochemistry* **15**, 4497; 1976) suggested that tau might consist of proteolysed fragments of HMW. From comparisons of amino acid composition and one-dimensional peptide mapping, Cleveland *et al.* conclude that tau I–IV are closely related to each other but not to the HMW material in their preparations. However, the results presented so far may not be sufficient to convince everyone; since a tau molecule derived from a specific region of HMW would correspond to only 20% of the original molecule, such a relationship would not necessarily be obvious from the present experiments.

One of the more interesting cases of abnormal assembly of tubulin is the formation, from unfractionated microtubule protein, of extended sheets, induced by low levels (0.25–1.0 mM) of zinc. This effect was first reported by Larsson *et al.* (*Expl Cell Res.* **100**, 104; 1976). The sheets offer an opportunity of observing the structure of an extended crystalline array of tubulin molecules by electron microscopy and applying image analysis techniques, including optical diffraction and computerised image reconstruction. Crepeau *et al.* (*J. molec. Biol.* **116**, 301; 1977) have carried out some preliminary studies in this direction, and have compared the structures of Zn-induced sheets and the smaller tubulin sheets formed under normal buffer conditions during microtubule assembly. In the

Zn-induced sheets, the relative arrangement of tubulin protofilaments appears to be different from that in the 'normal' sheets and in microtubules, but the protofilaments seem to be essentially the same.

The results show the structure in more detail than has been observed before, although the present resolution is still only about 20Å. Some preliminary studies on unstained sheets suggest that it may be possible eventually to achieve the sort of high resolution results obtained by Henderson and Unwin in their study by electron microscopy of the purple membrane from *Halobacterium* (*Nature* **257**, 28; 1975). □

## Primate social structure and ecology

from John Krebs

GIBBONS (*Hylobates* spp.) live in pairs and defend a territory of less than 1 square kilometre; baboons (*Papio* spp.) wander over an undefended home range of 15–20 square kilometres in polygamous or promiscuous groups of about 40 individuals. These contrasts in group size, home range, mating system and so on are typical of the bewildering array of social organisations in primates, and one of the major aims of primate ethologists over the past 15 years or so has been to seek regular patterns in the differences between species.

J. H. Crook and J. S. Gartlan (*Nature* **210**, 1200; 1966) made the first serious attempt to link primate social structure with a small number of ecological variables such as food dispersion and pressure from predators. They noted, to take just one example, that ground-living primates such as baboons live in larger groups than their arboreal relatives and suggested that this could be an antipredator adaptation, terrestrial monkeys being more exposed to predators and hence benefiting more from communal defence in a large group. Crook and Gartlan clearly had the right approach, but their attempt to classify primate societies into about half a dozen ecological categories foundered because as more field evidence came to hand, too many exceptions to their rules emerged. This led to two modifications of the original approach. Some argued that Crook and Gartlan were wrong to assume that primate social organisation is always adapted to present day conditions, and that phylogenetic heri-

## Nitrogen diffusion in diamond

from John Walker

THE results on conversion of diamonds from type Ib to type Ia which are reported in this issue of *Nature* by Chrenko, Tuft and Strong (page 141) have important implications for diamond physics and for synthesis of gemstones.

The Platonically ideal diamond is composed only of carbon. Real diamonds, however, contain impurities, and paradoxically, the large, regularly shaped and apparently perfect gemstones are usually the most impure. (This effect is well-known to crystal-growers—impurities affect the shape of many types of crystal.) In diamond the most important impurity is nitrogen. A diamond is classified as type I if it is appreciably impure, and as type II if it is relatively nitrogen-free. The nitrogen may be present as isolated individual atoms (type Ib), giving the diamond a yellow colour, a paramagnetic resonance signal and a characteristic infrared absorption; or it may be in aggregates, especially pairs (type Ia), resulting in no paramagnetism, no visible colour and a different infrared spectrum. This type-classification is qualitative, and diamonds of mixed type are often found, but it is useful nonetheless.

The vast majority of natural diamonds are type Ia, but synthetic crystals are usually type Ib. Nobody knows why for sure; a plausible hypothesis is that some natural diamonds at least, started life as type Ib, and were subsequently transformed to the Ia type.

Diamond is the metastable form of carbon at normal temperature and pressure. It is stable, and so can be synthesised, at higher temperature and pressure. The hypothesis is that, in some conditions, although nitrogen can be incorporated into the growing crystal, it is immobile; subsequent higher temperatures or lower pres-

ures allow it to become mobile and diffuse through the carbon lattice until it can aggregate with other nitrogen atoms. Chrenko *et al.* report that after annealing at 2,000 K and 60,000 atmospheres for 30 min the type Ib diamonds had become appreciably paler yellow in colour, due to reduction of their characteristic visible absorption, and that their paramagnetism was weaker. The infrared spectrum had changed from typical type Ib to mixed Ia and Ib, and the N3 ultraviolet absorption system (thought to be an aggregate of three nitrogen atoms) could be detected. The total nitrogen concentration remained constant—a useful consistency check.

What is the significance of these results? First, they tell us more about how nitrogen behaves in diamond; and they may help us to understand other defects, especially the 'platelets'—laminar defects on {100} planes which have intrigued and puzzled diamond physicists for 40 years. Second, they indicate a method of turning yellow synthetic diamonds into 'water-white' ones, thus enhancing their value as gemstones. Third, they tell us more about the synthesis process, which may lead to the commercial synthesis of large gem-quality diamonds. (At present, although tons of synthetic diamonds are produced annually, they are suitable only for industrial applications—it is actually cheaper to dig the gemstones out of the ground than it is to synthesise them.) Finally, the results may have implications for the conditions prevailing in the Earth's mantle that led to the natural synthesis of diamonds. As Sir Charles Frank put it, 'Nakaya has written a poem in which he says, "A snowflake is a letter to us from the sky." A diamond is a letter to us from the depths, and a letter more worth reading because we can visit the sky.'

tage plays a strong role (Struhsaker *Folia Primat.* **11**, 80; 1969) while others proposed that Crook and Gartlan were in principle right, but that the differences in ecological pressures had to be analysed on a much finer scale (Clutton-Brock *Nature* **250**, 539; 1974), and further that the same ecological pressure may lead to different solutions.

In an important new review, T. H. Clutton-Brock and P. H. Harvey (*J. Zool. Lond.* **183**, 1; 1977) have greatly extended and updated Crook

and Gartlan's original approach. They have classified all the primate species for which they could find data into nocturnal or diurnal, arboreal or terrestrial, and insectivorous, frugivorous or folivorous. They then did a quantitative statistical analysis to look for consistent differences between these ecological categories in features such as group size, home range, sex ratio and body weight. The main trends to emerge from their analyses were that nocturnal primates which are all arboreal and mainly eat either

fruit or insects, are small, live in small groups and have small home ranges; both diurnal and nocturnal fruit eaters have large bodies, and live in larger groups and home ranges than leaf eaters; and finally, diurnal terrestrial primates live in larger groups and ranges and have more marked sexual dimorphism than do diurnal arboreal species.

How are these general trends related to ecological needs such as food gathering and avoiding predators? Clutton-Brock and Harvey suggest that the nocturnal species have to have a small body because they feed by crawling on to small branches, and they rely on crypsis to escape from predators. At the other extreme, conspicuous terrestrial monkeys living in open habitats have evolved large body size partly as an antipredator device, and partly to allow them enough mobility to search over a wide area for scattered food. Although Clutton-Brock and Harvey agree with Crook and Gartlan's idea that large groups in terrestrial primates may be an antipredator adaptation, they also point out that there are large differences in group size within both the arboreal and terrestrial categories. They propose that larger groups are always advantageous in diurnal primates, perhaps as an antipredator device, but that competition for food sets an upper limit to group size, so that species feeding on large clumps of food can afford to live in larger groups than those eating more evenly scattered food. A comparison of two types of *Colobus* monkey, one of which eats fruit, flowers and shoots (highly clumped food), and the other which eats leaves of all ages (less clumped) supports the idea: the former live in larger groups.

Home range size is obviously closely related to group size and is probably determined both by the minimum area needed to support the group, and by the density and dispersion of food. Species feeding on evenly dispersed, fairly dense food supplies have small, often defended home ranges, while those eating widely scattered clumps of food tend to have large undefended ranges, for obvious economic reasons.

So far, the differences in social structure seem to be well explained by straightforward ecological pressures, but it is not so easy to account for the variations in mating system and adult sex ratio. Monogamy is very rare in primates, and it must presumably have evolved only when a male significantly increases his output of young by helping the female (for example, monogamous marmosets have twins and the male helps to carry them), or because the male cannot secure more than one

mate. (This may seem an unduly chauvinistic view, but the sad fact is that female mammals as a whole have little choice about who does the parental care.) The second of these possibilities may account for monogamy in species such as the gibbon in which the even distribution of food favours territorial defence, and males may be unable to defend enough food to support more than one wife. The majority of primates breed in harem or multimale groups, and the ecological factors favouring one system over the other (and the general bias of adult sex ratio towards females) are not at all clear. It is, however, apparent that strong sexual dimorphism ( $\sigma : \text{weight ratio}$ ) is related to the degree of bias in the sex ratio and to polygamous or promiscuous mating. This suggests that sexual dimorphism in primates has evolved when males compete for the chance to mate.

Clutton-Brock's and Harvey's review emphasises the fact that it is possible to account for many of the differences in primate social structure by pressures associated with detailed dispersion of food and vulnerability to predators. It also reveals that the various dimensions of social organisation, such as group size, sex ratio and so on, may be influenced by different ecological factors and should therefore be analysed separately. One of the next steps will be to see to what extent variations within a species in different habitats can be used to test the ideas generated by interspecies comparisons.

## Biochemical oscillators

from N. MacDonald

OSCILLATORY phenomena in organisms, with periods of seconds or minutes, are known in great variety. The most obvious example is the heart pacemaker oscillation in the membrane potential of the sino-atrial node. Oscillatory membrane potentials also occur in neurones, in cells secreting hormones, and in smooth muscle. The interpretation of such phenomena in terms of underlying oscillatory biochemical reactions presents a challenge to both experimentalists and mathematicians. Identification of the steps in a feedback loop is not sufficient, unless the likelihood of instability of the steady state is established. Formidable

difficulties arise from the nonlinear dynamics of enzyme-catalysed reactions, from the length of the chains of reactions in feedback loops, and from the linking of these loops in complex networks.

In seeking to reduce networks of reaction equations to manageable proportions one relies heavily on the fact that the time scales for biochemical reactions vary widely. Retaining for detailed study those reactions with relaxation times rather smaller than the period of the oscillation, the other reactions may be subsumed into parameters. Particular interest then attaches to the values of these parameters at which qualitative changes occur in the nature of the solutions of the equations retained. In mathematical terms, this is the field of bifurcation theory. Alternatively one may retain more equations, but classify them into fast and slow sets. Then it is necessary to explore situations in which smooth changes in the slow dynamics lead to qualitative changes in the nature of the fast dynamics. This is the field of catastrophe theory, as discussed in this context in the recent review by Heinrich, Rapaport and Rapaport (*Prog. Biophys. molec. Biol.* **32**, 1; 1977).

Both the review by Heinrich *et al.* and that by Goldbeter and Nicolis (*Prog. theor. Biol.* **4**, 66; 1976) are largely concerned with detailed models of oscillations in the glycolytic pathway. Here direct evidence of periodicity in the concentrations of chemical species is available, and a great deal of work has been done in constructing and testing models. The models examined in these reviews stress the activation and inhibition of the enzyme phosphofructokinase by one or more of the adenosine phosphates AMP, ADP and ATP.

Much progress has been made recently in the mathematical analysis of the single loop, end-product inhibited reaction sequence advocated by Goodwin (*Adv. in Enzyme Regulation* **3**, 425; 1965) as a paradigm for a biochemical oscillator. One highlight in this is the theorem of Hastings, Tyson and Webster (*J. Differential Equations* **25**, 39; 1977) which is applicable to a wide class of such loops, and allows nonlinearity in all the equations. This theorem states that instability of the steady state solution is a sufficient condition for the existence of at least one periodic solution, although unfortunately this solution need not be stable. Another highlight is the systematic application of approximate methods by Rapp and Mees (*Math. Biosciences* **25**, 165; 1975; *J. math. Biol.* **3**, 203; 1976 and in the press) to estimate periods and amplitudes of these solutions.

N. MacDonald is in the Department of Natural Philosophy in the University of Glasgow.

Factors tending to promote instability of the equilibrium point, and the onset of the attendant oscillations, are of three kinds. Strong nonlinearities, such as can be expected with allosteric enzymes, help. So do the presence of a large number of successive reactions in a loop, and the similarity of the time scales of all these reactions. These two factors go together, since widely different time scales allow some of the reactions effectively to be ignored. There is still a wide gap between the appealing idea of the end-product inhibited oscillating loop, now put on a firm mathematical basis, and the presentation of a fully worked out and experimentally testable scheme, possessing these factors, for some specific oscillator. End-product inhibition is rife in cell chemistry, but this can be understood solely in terms of advantageous properties of steady states. In a well-defined sense (Savageau *Biochemical Systems Analysis*, Addison Wesley, 1976) these states have minimal, which implies optimal, sensitivity to parameter change.

A bold attempt has recently been made by Rapp and Berridge (*J. theor. Biol.* **66**, 497; 1977) to implicate, in a wide range of oscillations, end-product inhibited loops involving the binding of calcium ions. They propose two different styles of loop, involving calcium in conjunction with cyclic AMP. In the first an increase of cyclic AMP causes an increase in cytoplasmic calcium, either by promoting calcium entry through the cell membrane, or by causing a shift in cell calcium from a bound state to the cytoplasm. Cytoplasmic calcium on the other hand is taken to inhibit the synthesis of cyclic AMP, acting through the inhibition of the allosteric enzyme adenylyl cyclase. The alternative loop reverses the activating and inhibiting roles of cyclic AMP and calcium.

Sustained oscillations have been observed in the transepithelial potential of the salivary gland of the blowfly *Calliphora*. Rapp and Berridge cite evidence that here cyclic AMP can release calcium from some intracellular store, and that this store may be in mitochondria. They also cite evidence that calcium can inhibit cyclic AMP synthesis in this gland, and that this may be by inhibition of adenylyl cyclase, for which there is evidence in certain cells of a variety of organisms. On the other hand, they argue that the second kind of loop may be responsible for the periodic contractions of smooth muscle. They also examine cardiac pacemaker oscillations, membrane potential oscillations in cells producing insulin, and signalling in the slime mould *Dictyostelium*.

In all these contexts their evidence is

cumulative, seeking to implicate calcium as significant in contexts in which oscillations occur rather than proposing detailed dynamics. It is a somewhat daunting thought that each context may require a similar amount of effort to that devoted to glycolytic oscillations over the years. But the work of Rapp and Berridge should focus critical attention on a particular set of possible common mechanisms for a variety of periodic phenomena. □

## Acceleration of auroral particles

from Alan Johnstone

AURORAL electrons are accelerated into the upper atmosphere by electric fields parallel to the magnetic field lines with the total potential difference sometimes exceeding 10 kV. The fact that the acceleration is caused by a quasi-static electric field, and the magnitude of the potential difference can be deduced from measurements of the angular and energy distributions of the precipitating electrons. The electric field increases the electrons' velocity parallel to the magnetic field leaving the perpendicular component unchanged. This creates an angular distribution which peaks in the downward direction parallel to the magnetic field. This contrasts with the angular distribution of the source population of trapped electrons which usually has a minimum along the field. All electrons are given the same increase in energy ( $e$  times the potential drop) so that any observed at lower energies must have been either backscattered from the atmosphere and then reflected from the potential, or scattered out of the beam by wave-particle interactions. As there are fewer of these electrons the energy spectrum develops a peak close to the energy corresponding to the potential differences. Sounding rockets and satellites have found that such electron distributions are common above auroral arcs. The acceleration is found to be greater in the centre of the arc than on the northern and southern borders implying that the equipotential surfaces in a meridional slice above the arc are V-shaped as in Fig. 1.

The accelerated electrons have been detected at altitudes up to 1,500 km and ions accelerated in the opposite

direction have been detected by Geostationary satellites near the equator, but the altitude where the particles were accelerated could not be located until the S3-3 satellite was put into an elliptical polar orbit with apogee at 8,050 km and perigee at 260 km in 1976. In a year of operation it has traversed the auroral zone at all altitudes between these extremes. Convincing evidence from this satellite that particles are usually accelerated somewhere in the range between 2,000 km and 7,000 km was one of the highlights of the recent IAGA meeting in Seattle. P. Mizera and J. Fennell (Aerospace Corp.) showed examples of upward-moving, magnetic-field-aligned ion beams accelerated below the satellite by several kiloelectron volts detected simultaneously with downward-moving electron beams accelerated by comparable amounts above the satellite (Fig. 2). This is a clear indication that the satellite is in the middle of the acceleration region. The ion beams include both  $O^+$  and  $H^+$  ions (Shelley *et al. Geophys. Res. Lett.* **3**, 654; 1977), confirming that they originate in the low-altitude ionosphere. The probability of observing an accelerated ion beam in a traversal of the auroral oval is as high as 95% at altitudes above 7,000 km and less than 5% below 2,000 km. What the data do not tell us is how the electric field is

**Fig. 1** A schematic diagram of the equipotential contours above an auroral arc. The innermost contours are negative so that electrons are accelerated downward parallel to the magnetic field  $B$  into the auroral ionosphere (Swift *et al. J. geophys. Res.* **81**, 3931; 1976).

Alan Johnstone is at the Mullard Space Science Laboratory of University College London.

distributed in this height range. It could all be confined within a narrow layer, as some theories require, or it could be distributed evenly over the entire length. If the layers are thin then at least two must exist on the same field line in order to give the simultaneous observation of upward accelerated ions and downward accelerated electrons. F. Mozer (Berkeley) presented measurements of the ambient electric field from the same satellite (see also *Phys. Rev. Lett.* **38**, 292; 1977). The magnitude of the electric field, in structures which he termed 'paired electrostatic shocks', was more than  $0.5 \text{ V m}^{-1}$  perpendicular to the magnetic field with a smaller parallel component. This is far greater than the field strengths found below 1,000 km. The structure in the paired electrostatic shock is just the same as would be found traversing the V-shaped potential of Fig. 1 and the potential difference between the centre and the edges can reach several kilovolts if it is treated as a purely spatial variation. The accelerated ion beams and paired electrostatic shocks are found in the same region but the detailed correlation is not close. The ions spread over a region more than five times the thickness of a typical electric field structure. If they were accelerated upward by a V-shaped potential distribution beneath observed electrostatic shocks they would only be found in the centre of the structure itself. The detailed comparison of the electric field and particle observations is still at an early stage. The results of analysis now underway will be interesting and significant.

These data do not discriminate between the various proposed physical mechanisms which could be maintaining the kilovolt potential differences. Until the observational evidence for parallel electric fields became overwhelming it was thought that the plasma conductivity was too great to allow potentials of more than a few volts to develop along a magnetic field line. Strong electric currents flow upwards along magnetic field lines above auroral arcs (carried by a downward flux of electrons) which may exceed the current density the plasma can support with low resistance. Three mechanisms have been proposed to explain the formation of high potentials with strong field-aligned currents. The electrostatic shock layer, which has been shown to exist as a shock-like solution to the Poisson/Vlasov equations for strong currents, has a thickness of the order of an ion gyroradius (D. Swift, Alaska). This is related to the double-layer, also current-controlled, but not much thicker than a Debye length. Anomalous resistivity

Fig. 2 Differential energy flux spectra for protons and electrons at 7,300 km altitude over the northern auroral zone. ○, Upcoming particles; ●, downgoing; △, mirroring. The mirroring electrons below the peak may be trapped between the converging magnetic field on one side and the electric potential on the other. (P. Mizera and J. Fennell, Aerospace Corporation).

is created when the current flow becomes unstable to the generation of electrostatic ion cyclotron waves. The resultant electrostatic turbulence hinders the electron flow. Finally, high voltages can be required to drive a current in a hot plasma down the converging field lines against the magnetic mirror force.

Evidence for all three mechanisms can be found in the S3-3 data but none of it is conclusive. C.-G. Fälthamar (RIT, Stockholm) suggested that more than one of them may be operating. For example, the plasma turbulence associated with anomalous resistivity may help the formation of a shock layer.

If it is becoming clearer how the parallel electric fields might be maintained, it is still not clear how the contours above the V-shaped layer in Fig. 1 close, and where the energy source which drives the field-aligned currents is to be found. It was noticeable at the IAGA meeting that most scientists discussing auroral acceleration mechanisms ignored those regions of the magnetosphere above the acceleration region and that those con-

cerned with auroral substorm-related events in the far plasma sheet and geomagnetic tail ignored the influence of the ionospheric ends of the magnetic lines of force. The time has come to try to fit the two ends together. □

## Microanalysis in biology and medicine

from Patrick Echlin

The Third International Conference on Microprobe Analysis in Biology and Medicine was held in Münster on 5-8 September, 1977 under the auspices of the German Electron Microscope Society and the Royal Microscopical Society. The papers will be published by Hertzl-Verlag, Stuttgart, later this year.

THE previous meetings in 1973 and 1975 showed that a wide range of microbeam analytical techniques could be used in biological investigations. The meeting in Münster demonstrated that the methods are at last providing physiologically significant data from a wide range of plant and animal tissues, which are in close agreement with similar data obtained using ion selective electrodes, flame photometry and chemical analysis.

In many instances microbeam techniques are taking analysis beyond the limits of more conventional methods, as was clearly shown in papers on the application of electron probe X-ray microanalysis to cells and tissues. T. Hall (University of Cambridge), claiming that the spatial resolution was now as low as 20 nm and the performance better than  $10^{-18} \text{ g}$  of an element, showed how X-ray microanalysis could be used for quantitative analysis of diffusible ions in frozen-hydrated sections of fluid-transporting epithelia. A. Somlyo (University of Pennsylvania) was able to show, using freeze-dried sections of smooth muscle, that the high cellular chloride in this tissue was not due to compartmentalisation in organelles and that the sarcoplasmic reticulum is a major storage site of calcium in both smooth and striated muscle.

G. Kirk (University of Chicago) demonstrated how the electron probe could be used in the analysis of single cells, by showing how the membrane transformations which distinguish red blood cells with a naturally high level of potassium from those with a

Patrick Echlin is an Assistant Director of Research in the Botany School in the University of Cambridge.

naturally low level of potassium occur early in the differentiation of the erythroblastic stem cells. A. Lauchli (Technical High School, Hannover) using frozen-hydrated bulk root tissue, has shown that sodium is reabsorbed from the vessels in the proximal regions of the roots of certain plants.

Discussions on specimen preparation for microanalysis led to the conclusion that, with the possible exception of tightly bound elements, conventional wet chemical procedures were to be avoided and that low temperature techniques involving frozen-hydrated or frozen-dried sections, bulk samples or microdroplets of cell fluids were to be preferred. The only compromise might be to use freeze-substituted material or to encapsulate specimens in high molecular weight cryoprotectants before freezing. P. Echlin *et al.* (University of Cambridge) demonstrated that these polymers, which do not enter the cell, limit the size of intracellular ice crystals to nanometre dimensions, and do not seem to cause any significant loss of elements from cells and tissue, although some elemental redistribution may occur within the cell. The extent of elemental redistribution generally remains a problem, but there was agreement that valid elemental concentrations can be measured between different cell compartments, although it is probably premature to try and measure gradients and variations in concentration within a given compartment.

Several papers dealt with the quantification of analytical results. J. Russ (Prairie View, Illinois) described a new and relatively simple computer program for processing and displaying elemental spectra obtained from thin biological samples, and T. Appleton (University of Cambridge) discussed ways in which analytical information obtained from frozen-dried sections could be related to the fresh hydrated state. B. König (Batelle Institute, Frankfurt) considered the optimal conditions for high spatial resolution in the analysis of thin films and R. Bauer (University of Munich) gave details of a program for thin sections of biological tissues which separates elemental peaks and background radiation by means of artificially generated spectra. Using this technique together with internal albumin standards, R. Rick (University of Munich) found evidence for a syncytial sodium transport compartment in all epithelial layers of frozen-dried sections of frog skin epithelium.

There have been significant advances in the development of the laser microprobe mass analyser. R. Wechsung (Leybold-Heraeus, Cologne) gave details of a commercially available in-

strument with a spatial resolution of  $0.3\text{ }\mu\text{m}$ , detection limits of  $10^{-20}\text{ g}$  within the  $0.1\text{--}100\text{ p.p.m.}$  range and the capability of analysing both organic and inorganic material. F. Hillenkamp (University of Frankfurt) and R. Kaufmann (University of Düsseldorf) demonstrated how the instrument could be used to analyse trace elements and physiological cations and anions or for fingerprinting organic constituents.

Unfortunately, this high level of sophistication is still missing from the techniques of cathodoluminescence, and in the nuclear and proton probes. These techniques, together with ion probe analysis, still need further development particularly with respect to improving their spatial resolution and their biomedical applications. These are clearly the analytical techniques of the future and for once the biologists are ready to use them, having firmly established valid preparative methods based on low temperature techniques. □

## Economy and chemistry of phosphorus

from P. B. Tinker

A symposium, entitled The Economy and Chemistry of Phosphorus was held at the Ciba Foundation on 12–15 September, 1977, and chaired by Professor R. J. P. Williams. The Proceedings will be published by the Ciba Foundation.

PHOSPHORUS occupies a special place amongst the elements which are essential to life, because of the variety and complexity of the processes in which it takes part. The wide-ranging symposium was therefore of the broadest interest.

The first and most basic topic was supply, since there have been suggestions that phosphorus is a mineral resource which may be near exhaustion. Several speakers stressed the underlying problem of the explosion of population and economic expectations. The present facts are not in dispute: current production is some 15 million tons each year, rising on a long term trend of 6–7% per year, from minimum demonstrated reserves of some 6,000 million tons, which suggests exhaustion in 50 years. However, real reserves must be far larger, and J. W. Brinck (International Resources Consultants,

Alkmaar), used a modelling approach to infer that there could be anything from 40,000 to 500,000 million tons in all. Even this largest value would be exhausted in 120 years if the trend continues. As with all futurology, the numbers are so inexact that one can do little except show that rising trends cannot be sustained for ever. The real question is the mechanism by which these rising trends are stopped. As Brinck remarked 'Doomsday is always 70 years ahead,' and the best estimate seems to be that we have enough phosphorus in mineable reserves to take us beyond the limit of useful prophesy, especially since recent price increases have sharply reduced consumption. Possible technical developments in mining technology, the use of sea-floor phosphatic nodules, greater efficiency in the use of fertilisers and phosphorus recycling make prediction especially difficult, and it was suggested that our problems are more likely to be the familiar ones of ill-directed investment or the exercise of monopoly power. The analogy with oil springs easily to mind, but it is not really a good one: oil has several substitutes, although its withdrawal would be catastrophic at once, whereas phosphorus could be cut off without serious immediate harm, although it has no substitute at all.

By far the greatest part of mined phosphate is used for fertilizers, and G. H. McClellan (International Fertilizer Development Center), described the technology of their production, stressing how this affected the possibility of using low-grade ores.

The phosphorus cycle had a good run, with E. J. Griffith (Monsanto) discussing it on a global scale, J. C. Bowman (University of Reading) giving very detailed data for Britain, and A. F. Harrison (Natural Environment Research Council) dealing with discrete ecosystems. Natural ecosystems of forest and grassland have most of their phosphorus stored in the soil, with very small outputs and inputs, whereas the cycle in agriculture is much more 'open', with large inputs (as fertilizer) and outputs (as harvested crop). However, it is incomplete, in the sense that the inputs exceed outputs by a factor of between 2 and 10, due to adsorption of phosphate in the soil. It became quite clear during the meeting that this is the central problem in the world phosphorus economy, which consists largely of digging out phosphorus at one place and storing in the soil at another. The magnitude, value and use of this phosphorus store is not wholly understood, since the physical chemistry of phosphate in soil is extremely complex, but it is crucially important.

R. J. P. Williams (University of

P. B. Tinker is in the Department of Soils and Plant Nutrition at Rothamsted Experimental Station.

Oxford) introduced the consideration of the detailed role of phosphorus in biology, noting the vital functions it performs in the transfer and storage of information (as nucleic acid) and energy (as ATP) and in compartmentation (as phospholipids). B. C. Loughman (University of Oxford), followed with a detailed description of the uptake and metabolism of phosphorus by plants, the most notable point being the enormous ability of organisms to concentrate phosphate from extremely dilute solutions. This is important in the utilisation of 'soil store' phosphate, and crops can take this up, although it may not be able to support maximum yield. There is some possibility of breeding crops which are more efficient at absorbing low-solubility soil phosphate, and microbiological systems such as mycorrhizas are often able to assist phosphate uptake.

The importance of this uptake ability of organisms was illustrated by the very interesting and occasionally contentious section dealing with eutrophication of surface waters by phosphorus wastes—largely from detergents in sewage. The discussion centred on the Great Lakes, and G. R. Alexander (US Environmental Protection Agency) discussed the problem in general and political terms. There is agreement that phosphorus is the limiting element in all five Great Lakes, and removal of phosphorus from sewage inflows has proved unreliable. He saw little chance of stopping any of the other sources of supply, such as topsoil erosion, and a ban on detergent phosphates in sensitive areas would be the easiest method of improving the position. Members of the relevant industry naturally did not entirely agree. A much more relaxed view was taken by R. W. Collingwood (Water Research Centre, Medmenham Laboratory), who felt there was no justification for the high cost of removing phosphate from sewage in Britain. Our disposal problems are very much easier than those in America, and he emphasised that each case should be treated on its merits, rather than imposing blanket bans. The subject is extremely complicated, including political judgement of what 'eutrophication' is acceptable, and the great difficulty of predicting exactly what may happen in the sometimes complex ecosystems of lakes. On the whole, the real damage to the community resulting from either algal growth in rivers or from the withdrawal of polyphosphates in detergents seemed rather small in relation to the often passionate interest aroused by it. The very useful point was made that 'eutrophication' is really a state of higher biological productivity, which may be positively desirable, and that we should not

simply assume that the less phosphate the better, without thought.

The chemistry of phosphorus underlies all the other topics, though it was difficult to deal with it in depth in such a broad-based meeting. A. J. Kirby (University of Cambridge) discussed the fundamental facts of the transfer of the phosphate group, which is the essence of its biological importance. This deals with the P-O bond, and contrasted with the paper of T. D. Inch (Microbiological Research Establishment, Porton Down), who discussed the interesting compounds with P-C bonds. The phosphonates are important in the nerve gases and pesticides based on these, and they do occur in both plants and animals, though in very small amounts. Some of their substitution reactions are interesting in giving a retention of steric orientation.

R. J. P. Williams finally wound up the Conference, with a look back at the problems of unwanted phosphorus storage, and the desirable and undesirable growth resulting from its presence. The meeting produced no radically new ideas, but it formed an excellent synthesis of the state of knowledge at present. The wide spectrum of disciplines and interests made the discussion always interesting, sometimes fascinating, and showed up very clearly the different mental approaches, for example between the pure chemists and the 'field' scientists. □

## Photosynthesis at Reading

from J. Barber and B. Halliwell

The Fourth International Congress on Photosynthesis was held at Reading on 4-9 September, 1977. The Congress dealt with all aspects of research into photosynthesis under two broad categories; the light reactions, and carbon metabolism (including the physiological and applied aspects of the subject).

A SERIES of symposia brought together biophysical and biochemical work aimed at understanding how energy capture, transfer and trapping occurs in photosynthetic organisms. This area is highly active at the moment due chiefly to the development of new techniques and to the increasing use of

sub-chloroplast particles and purified reaction centres from photosynthetic bacteria. For example, G. Searle (Imperial College, London) reported how time-resolved transfer sequences between different pigments can now be studied in photosynthetic tissue using picosecond fluorimetry. P. Thornber (University of California, Los Angeles) emphasised that picosecond absorption studies are also providing valuable information on primary charge separation in bacterial reaction centres, and in particular referred to recent work with *Rhodospseudomonas viridis*. As yet, purified reaction centres from  $O_2$ -evolving organisms have still not been isolated and direct comparisons between these systems and the photosynthetic bacterial system can only be speculative.

Although the 'Z-scheme' for electron flow in  $O_2$ -evolving systems seems to be the best working model, there is still confusion about the role of cytochrome  $b_{559}$ , cytochrome  $f$  and cytochrome  $b_6$ . The function of these components must be understood before it can confidently be said that a full description of electron transport in photosynthesis is known. Moreover there may be other electron transfer components which have not been identified. The existence of a new component was suggested at the congress by R. Malkin (University of California, Berkeley). He reported that a 'Rieske' iron-sulphur centre exists in chloroplasts and from several lines of evidence suggested that it functions as an electron carrier between the plastoquinone pool and plastocyanin. Plastocyanin now seems to be fully accepted as a major electron carrier in chloroplasts and at the meeting the results of high resolution X-ray analysis of its structure was reported for the first time by H. C. Freeman (University of Sydney). Knowledge of the mechanism by which molecular oxygen is generated from water by light energy is progressing steadily. T. Wydrzynski (University of Illinois) presented some new results obtained with colleagues based on NMR studies. Their results suggest that the 'S-state enzyme' of the 'Kok-clock-model' contains four manganese atoms and is advanced by  $Mn^{2+}$  to  $Mn^{3+}$  changes. Whether their model is correct or not is open, but efforts to gain a chemical understanding of the reactions involved are welcome and moreover their model fits with studies of flash-induced  $H^+$  release presented by others at the meeting.

### Photophosphorylation

The symposium concentrating on photophosphorylation clearly demonstrated that in its broad terms, Mitchell's chemiosmotic scheme is ac-

J. Barber is in the Department of Botany at Imperial College, London, and B. Halliwell is in the Department of Biochemistry at King's College, London.

cepted by most workers. A few papers were presented which disagreed with some of its finer points and the exact values of the H/e or P/e ratios are still not known. Over the years H. Witt (Berlin) and his colleagues have presented strong experimental support for Mitchell's concepts and again at this meeting, Glaber from Witt's laboratory reported experiments in which ATP synthesis had been induced by creating artificial electrical gradients across chloroplast membranes. A requirement of the chemiosmotic scheme is that there is a membrane-located ATP synthetase or coupling factor able to do work when translocating protons down their electrochemical potential gradient. The coupling factor consists of several subunits and N. Nelson (Haifa, Israel) reported some unique experiments. He seems to have isolated the 'H<sup>+</sup>-ionophore' component of the complex and has tested its ability to increase H<sup>+</sup> conductance by incorporating it into artificial membrane systems.

### Carbon metabolism

The sessions on carbon metabolism dealt largely with the regulation of CO<sub>2</sub> fixation in C<sub>3</sub> plants and with photorespiration. No great advances in our knowledge of C<sub>4</sub> metabolism were reported, but it is now generally accepted that the Calvin cycle operates only in bundle-sheath cells. CO<sub>2</sub> is fixed in the mesophyll, transferred to the bundle-sheath as malate or aspartate and released again to be refixed by the Calvin cycle.

Regulation of the Calvin cycle is achieved by several mechanisms, one of which is a light-dependent increase in the activity of certain enzymes. Illumination generates dithiol groups within the chloroplast, which then activate the enzymes. L. Anderson (University of Illinois, Chicago) and B. Buchanan (University of California, Berkeley) gave evidence that both membrane-bound dithiol groups and the dithiol protein thioredoxin seem to

be involved. A tentative mechanism may be proposed (Fig. 1).

As. H. Heldt (University of Munich) reported, when chloroplasts are illuminated, the Mg<sup>2+</sup> concentration of the stroma increases by 1–4 mM and its pH from 7.0 to 8.0 as H<sup>+</sup> enters the thylakoids and Mg<sup>2+</sup> moves out. These changes regulate several enzymes of the Calvin cycle, especially fructose and sedoheptulose diphosphatases. Both enzymes work best at high pH and Mg<sup>2+</sup> concentration. Ribulose diphosphate carboxylase requires preincubation with Mg<sup>2+</sup> and CO<sub>2</sub> to obtain maximum activity *in vitro*; it is not clear if the enzyme is always fully activated *in vivo*. According to D. Walker (University of Sheffield) the kinetics of the activated enzyme can now account for observed rates of CO<sub>2</sub> fixation. J. Preiss (University of California, Davis) suggested that starch synthesis is regulated at the level of ADP-glucose pyrophosphorylase, which is activated at high phosphoglycerate/inorganic phosphate ratios.

Illuminated chloroplasts generate H<sub>2</sub>O<sub>2</sub> but contain no catalase activity. Ascorbate peroxidase together with glutathione reductase may remove H<sub>2</sub>O<sub>2</sub> *in vivo*, an argument put forward by D. Groden (Bayreuth) and by B. Halliwell (King's College, London).

Photorespiration is caused by the formation of glycollic acid and its subsequent oxidative decarboxylation. G. Lorimer (Munich) reported experiments with <sup>18</sup>O<sub>2</sub> which show that most, if not all, of the glycollate is produced by the hydrolysis of phosphoglycollate generated by the oxygenase activity of ribulose diphosphate carboxylase. U. Heber (Dusseldorf) also carried out other experiments which supported this conclusion. The glycollate so produced is oxidised to glyoxylate and transaminated to glycine in peroxisomes. The glycine is converted into CO<sub>2</sub>, NH<sub>3</sub> and serine in mitochondria. As A. Moore (King's College, London) explained glycine oxidation by leaf mito-

## A hundred years ago

THE chief signal officer of the U.S. army has been urging that physical observations of the sun be made, as of sun-spots, faculae, protuberances &c., in reference to their supposed influences upon terrestrial meteorology, and has offered to publish the results monthly, or such of them as may be considered desirable by the observer, in the *Monthly Weather Review*. The United States Naval Observatory at Washington has already accepted this proposition, and it is considered very desirable that some other observatories in the east and at least one on the western coast, cooperate in this undertaking.

From *Nature* 17, 8 November, 39; 1877.

chondria has a P/O ratio of 3; the NH<sub>3</sub> formed is probably a substrate for glutamine synthetase. Several groups of workers have shown that the amount of carbon flowing through glycine and serine in illuminated leaves is more than sufficient for glycine decarboxylation to account for observed rates of photorespiration (D. Canvin, Queen's University, Ontario; C. Whittingham, Rothamsted). However, Canvin also reported that the <sup>14</sup>C-labelling kinetics of glycine and serine are extremely complicated and inconsistent with a single origin for these amino acids, so it cannot be clearly stated how much photorespiratory CO<sub>2</sub> arises by glycine decarboxylation.

Refixation of CO<sub>2</sub> released by photorespiration consumes considerable energy within the leaf. G. Krause (Dusseldorf) thought that photorespiration may help to use up 'excess' light energy and protect the chloroplast from damage. As. E. Elstner (Munich) explained, the electron acceptor complex of photosystem I can reduce O<sub>2</sub> to O<sub>2</sub><sup>-</sup>, the toxic free-radical superoxide (Elstner, Asada). In the absence of CO<sub>2</sub> NADPH/NADP<sup>+</sup> ratios in the chloroplast will be high and so electrons should be shunted more rapidly to O<sub>2</sub>. Photorespiration, by making CO<sub>2</sub> continuously available for refixation, might help to decrease O<sub>2</sub><sup>-</sup> formation to a level that can be dealt with by the chloroplast's protective mechanisms. □

Fig. 1 Tentative mechanism for activation of Calvin cycle enzymes by dithiol groups generated by illumination of chloroplasts.

# Book Review Supplement

THIS year marks the centennial of Edison's phonograph; next year is the centennial of the Edison Electric Light Company (which General Electric claim as their birthdate); and 1979 will mark the hundredth anniversary of Edison's incandescent bulb. It would be possible to go on to suggest plausible Edison celebrations for each year well into the twenty-first century, thus giving strength to the claim that here we have the most prolific inventor of all time. Furthermore, many of his discoveries were fundamental contributions to devices which now dominate our lives, thus giving firm support to Mr Clark's subtitle.

The perspective of a hundred years should make it possible for the author, as promised on the jacket of the book, in writing about Edison "to present him clearly against the background of his times and to assess fairly what his achievements really were.". There are occasions in the book where a gesture is made in this direction—as on p14 where Edison's characteristics are equated with those of his age, or in the few instances of reference to the financial manipulations of his robber-baron contemporaries. But none of this is pursued. There are no fresh insights into the relationships between Edison and his family, or Edison and his workmen, or Edison and people like Jay Gould. There is the suggestion that after his first wife died his re-marriage to someone quite different significantly affected his attitude towards his work (p146). But even this is not amplified, and references to his work habits in later years seem to indicate a single-minded dedication virtually unchanged from the earlier period.

What we have, therefore, is a pleasantly readable biography, conventional in form, which offers no special commentary beyond what is available in other works. To me, it is not as satisfactory as the biography by Matthew Josephson, published almost twenty years ago (*Edison*, McGraw-Hill, 1959). This is partly due to the fact that Josephson allowed himself twice as many pages as Clark, partly due to the research he did on the Edison papers, and partly due to his familiarity with that period of American economic history. But Clark's biography shares with Josephson's a major failing in not describing in any significant detail the inventions that lay

at the heart of Edison's life. It is therefore difficult for the reader to assess the nature of the challenges facing Edison, or the ingenuity with which he solved them. There are a number of other more specific failings as well, and it seems worthwhile to mention a few of them here.

There is, for instance, the marvellous story of how Edison received a telegram from London in December, 1878, urging him to develop a telephone receiver that would circumvent the

additional thought and experimentation, and called for some assistance, there is no reason to believe he would turn the entire laboratory over to the project. Furthermore, during January, in the middle of this three-month period, Edison produced his first high resistance lamp.

Clark's account of the development of Edison's carbon-resistance telephone transmitter is not so much in error as it is misleading. Although noting (p58) that the patent application was made in 1877 and not granted until 1892, he dismisses the delay by stating merely that "it is symptomatic of the controversial situation." This was a very important invention (as Clark recognises), and it would seem reasonable to include some discussion of the controversy and of the parallel work of Emile Berliner, Francis Blake, and others.

Nicola Tesla, that most peculiar electrical genius, is given credit (p159) for developing the transformer and motor that made alternating current transmission practical. Although there is a considerable amount of truth to the statement, it suffers greatly from oversimplification, and a few qualifying words would seem in order. This is especially relevant because for the period in question—the late 1880s—the important work (on the transformer) was carried out by William Stanley for Westinghouse, with some debts owed to earlier activities in Hungary and Britain. On the same page, Clark relates that in 1912 Edison and Tesla were offered jointly the Nobel Prize in Physics, that Tesla spurned it because of his ill feelings towards Edison, and that it therefore went to someone else. This is a story that has several versions; the one which is Clark's source even has the date wrong. Whether the Nobel committee contemplated giving the prize to them is unknown, but in November 1915 the *New York Times* printed an account that this was the case. Others followed, and there were of course interviews with the two principals. No known statements by Tesla indicated any reluctance to accept the award; when asked why Edison might be honoured, he responded that Edison was worthy of a dozen Nobel Prizes.

The whole matter of the AC-DC controversy is given some prominence by Clark—and rightfully so—as marking a change in Edison's way of

## Ushering in the electronic age

Bernard Finn

*Edison, The Man Who Made the Future.* By Ronald W. Clark. Pp.256. (Putnam: New York; Macdonald and Jane's: London, 1977.) \$12.95; £6.95.

Bell patent. (Unmentioned is the fact that in Britain Bell's patent protection extended only to the particular devices invented, whereas in America he was allowed credit for the principle of voice communication by a fluctuating electric current.) In a *tour de force* that was so typical for him Edison did what was asked. He shipped off a working model within three months, thus allowing his supporters in England to arrive at a profitable understanding with the opposition. Clark tells this story, and tells it well. After noting, however, that this was a time when intensive efforts were being expended on the incandescent lamp, he tries to make a point about Edison's methods of operation, stating that he "acted promptly and ruthlessly. He withdrew all his men from work on the electric light and put them on telephony." (p59). But this was surely not the case. The new receiver (which depended on the varying amount of friction that was produced when a varying current passed between a rotating drum and a stylus pressed on it) was directly related to an earlier telegraphic instrument he had invented; and although Edison undoubtedly expended a good deal of

Photo: Edison National Historic Site, Orange, New Jersey

Edison with two of the lamps produced to illustrate the Edison effect, later to become the basis of the electronics industry

thinking. This was during the period, already mentioned, when he remarried; an analysis of how various pressures then came to bear on Edison, and how he reacted to them, would make extremely interesting reading. Unfortunately, there is no real attempt to do this. Even the account of the succession of events is marred by errors of omission and commission. For instance, unmentioned by Clark, there were some very good reasons supporting Edison's side of the argument: storage batteries could be used in conjunction with direct current generators to even out the load cycle, and no motors had (yet) been invented to work on alternating current. The eventual capitulation—a merger with Thomson-Houston—is presented (p179) as if Edison were completely unaware of what was transpiring. Although it is true that Edison was against the merger and was largely kept in the dark, he had been aware for some time of the state of negotiations. His strong reaction, cited by Clark, was to the revelation of the final details, which merged everything together and stripped his name from the resulting firm title of General Electric.

There is no reason to believe (p65) that weakness in theoretical training

caused our hero to miss an opportunity to exploit the Edison effect. This was his discovery in 1883 that negatively charged particles were given off by his lamp filaments, and that they could be attracted to a positively charged extra electrode. He carried out a number of experiments and then applied for a patent where the effect was used in a sensitive current detector—the only use he could see for it. The experiments were known to physicists and electricians throughout the world, and none had a better suggestion. John Ambrose Fleming experimented with Edison-effect bulbs over the next few years before also abandoning them. It was two decades after the discovery (1904) before Fleming applied the Edison effect to act as a moderately effective detector of radio waves, and another decade before such a device (with a third electrode, added by Lee de Forest in 1906) was successfully used in an amplifier, thus ushering in the electronic age.

There are numerous other examples of this same type, and if one were to draw a moral from them I suppose it would be that scientific and technical biographies are very difficult to write. Further evidence for such a statement is the fact that very few have been written. If anyone should know this, it should be Mr Clark, who has specialised to a degree in this sort of writing. In his recent biography of Einstein he minimised the weakness of his own scientific background by doing a considerable amount of legwork, seeking out unused written material and interviewing people, to provide the makings of a dimension to the person he was describing that had not been available before. This could have been done with Edison. If Clark had used his strengths as a biographer to probe Edison's character and his dealings with other people, then the results might have been of great interest.

The fact of the matter is that the corpus of Edison material—most of it preserved at the historic site in West Orange, New Jersey—is enormous. The task of dealing with it intelligently in its present form, in spite of the amount of organising effort that has already gone into it, is far beyond the capacities of any one person. A fitting centennial tribute to Edison would be the inauguration of a project to develop these papers in a more useable fashion and to make them more widely available. There is hope that this will happen. If it does, the next biographer will be able to reveal to us a great deal more about the man who made the future. □

# Evolving a good bedside manner

Don Brothwell

*Origins: What New Discoveries Reveal About the Emergence of Our Species and Its Possible Future.* By Richard E. Leakey and Roger Lewin. Pp. 264. (Macdonald and Jane's: London; Dutton: New York, 1977.) £8.95; \$17.95.

THERE is perhaps some wisdom in the idea that before books are written, the authors should discuss the contents with potential reviewers. In the case of a detailed monograph or lavishly illustrated coffee-table book, one knows pretty well where one stands in terms of how to review it. In the first case one evaluates it particularly in relation to the limited number of specialist academics or students who will consider it; at the other extreme, the acid test is whether it will hold its own against Scotch, conversation or the television. But the hybrid is a problem, and that is really what *Origins* claims to be. The publishers tell us that it is "handsomely illustrated and fascinating to read" as well as being "filled with controversial ideas and fresh insights". Oh dear, a difficult one, pitched at the general reader but putting out new ideas which are presumably for professional eyes as well. The only answer is of course to try and play the same game. Is it pleasant reading for any of us interested in the evolution of our species (and most of us pretend to be, even though the state of 'advanced' societies suggests that few really are)? Secondly, does it really contribute something new to this well-trodden field, beyond a few new pictures and a few extra basic facts (easy enough to produce in human palaeontology)?

But to begin at the beginning, the sequence of chapters follows a pattern which is fairly standard now in books concerned with the evolution of man. We see primate evolution scaled against the few thousand million years of emergent life generally, a fact which should really put us firmly in our place and give us a strong perspective for viewing the biosocial absurdities of our own species; but it never seems to. The history of evolutionary controversy and theory is scanned briefly, reminding one that bias is all too easy and that there is a need for a detailed study of the history of palaeoanthropology, with

not only Darwin, Huxley, Owen and Dart, but also Elliot Smith, Ruffer and many others who were not only concerned with evolutionary theory but were also working on such questions as neurological change and ancient disease—exotic perhaps to some but just as relevant to the proper appreciation of the biology of past hominid populations.

Viewing the primates as a whole over their seventy million years or so of evolution is also an exercise of use to the hominid palaeontologist, setting his own distinctiveness and rates of change against that of other species within the Order. There are clearly explosions of adaptive success; first the prosimians, then monkeys, followed by a rather modest hominoid (ape-plus-human) differentiation, and finally the population explosion of modern man himself. In the interests of easy reading, considerable opportunities are missed for showing the questionable nature of much of the work and findings in this field, and the great research challenge which remains. But this is always the problem in popularising science, and although perhaps a lot of the fun of research is in the uncertainties, challenges and points of disagreement with colleagues, perhaps this does not lead to good reading at a general level? I confess that I think it does, but admittedly detailed and truthful revelations about some controversial issues would have to be very skillfully and carefully written indeed in order to avoid multiple libel actions.

Although much of the book seems to highlight Africa as a focal area of palaeoanthropology, the chapter on hominid beginnings rightly points out that most apparent ramapithecine material, a possible early hominid of about ten million years ago, is found outside Africa. This seems to be a rather neglected yet very significant fact, and if this group is indeed part of a variable stock from which the later hominids were derived, there is no reason why, in the following three or four million years, this group could not have given rise to advanced hominids in Europe or Asia, rather than Africa alone.

The next chapter, "The Cradle of Mankind", is concerned with a further morphological phase seen in human evolution—the australopithecine and *Homo habilis* groups of Africa. But how can one be sure, in this early stage of field-working world Plio-Pleistocene deposits, that many sediments out of Africa will not eventually produce these or related hominid varieties? And even if relevant fossils do not appear soon in other continents even though many more do in Africa, what does this

mean? From the evidence of skeletal material excavated in Britain, one would have to conclude that the Scots and Welsh hardly existed and only southern Britain was generally populated over the past few thousand years—a fact really correlated with soil acidity rather than historical demographic truth.

As expected, the fossils grouped under the name of *Homo habilis*, and especially the 1470 skull from Lake Turkana, are discussed in some detail. The fact that a number of deposits have now produced evidence of this "primitive *Homo* of nearly four million years old" is certainly interesting but whether "Just a few years ago no-one in their right mind would have believed this possible" seems debatable. I for one considered it possible and am not noticeably of unsound mind.

If one views human evolutionary studies from the turn of the century, it can be seen how the timescale has been greatly extended. In this respect at least, we tend to be rather conservative, although there seems to be an easier acceptance of much larger dates now, and indeed there is perhaps even a growing feeling that we must give as much time as possible for the mosaic of changes we know to have taken place in the limbs and pelvis, skull and brain. For, whereas Sir Arthur Keith, writing fifty years ago, could consider morphological evolution as if it were a sequence of easy growth changes, we must now see it as a complex product of multiple gene pool changes linked with environmental demands and social development.

Early tools are rightly given space in various parts of the book, and the comments on the early evidence is of course especially interesting. The great problem is to know what some of these roughly made objects really mean in terms of cultural development in the community. We can watch nest construction in birds or object manipulation in chimpanzees until we are blue in the face and still be quite unable to usefully interpret the significance of a remnant stone technology in another species where the brain is known only from an endocast. What is particularly tantalising is that one suspects that tools such as the poorly manufactured quartz objects from the Omo River Valley are telling us more than we can yet cope with in terms of early hominid perception and language development, the education of the early hominid child into the practicalities of hunter-gathering, and even the emergence of more advanced forms of group co-operation.

With the discovery of the fairly complete *Homo erectus* cranium from

East Turkana, doubts as to the considerable antiquity of this species are rather cleared away. (Claims for an earlier date from Java have been viewed with some uncertainty.) Whether Turkana Man was "very similar" to Peking Man is rather debatable, but that does not affect the importance of this find, and I would have liked to read more comments on this and related African specimens. For that matter, the authors could have usefully drawn in more of the *Homo erectus* and later Middle Pleistocene specimens which have been discovered in the past decade or so; and indeed I felt that the book sadly underplayed some discoveries in non-African areas of the world. I confess to being reluctant to accept their scheme for the emergence of *Homo erectus* in East Africa and then derive European and South-East Asian representatives from this stock. Perhaps this is only the result of a suspicious mind refusing to believe that the early hominids of between two and five million years ago were so restricted to Africa.

More than one chapter is concerned with this level of evolution and in the

one on "Intelligence, Language and the Human Mind" the authors give an opinion that "the vocal apparatus of *Homo erectus* would have enabled him to speak in a slow and rather 'clumsy' fashion". This brief but understandable comment is perhaps the essence of popular writing and perhaps does no harm, even though it is very misleading as regards the certainty of this fact and the lack of good evidence to substantiate it.

After considering the more recent phases of human evolution, including such aspects as population increase, agriculture, aggression and rituals, the authors are still able to conclude optimistically. And perhaps it is all to the good if palaeoanthropologists do cultivate a good bedside manner, cheering us on instead of placing us in the shadow of the dinosaurs. Unfortunately, I suspect that our mission may eventually be that of Job's comforter.

Leakey and Lewin have produced a nice book for the general reader, not one for the student or professional. □

Don Brothwell is Senior Lecturer in the Department of Human Environment at the Institute of Archaeology, London, UK.

## Fanatical system-builder

A. J. Cain

*The Spirit of System: Lamarck and Evolutionary Biology.* By Richard W. Burkhardt, Jr. Pp. 285. (Harvard University: Cambridge, Massachusetts and London, 1977.) £11.55.

It is a great relief to have at last a good book on Lamarck in English, neither partisan through patriotism, nor distorted by dislike of Darwin. Burkhardt gives us an excellent introduction to Lamarck, his contemporaries and predecessors, and to the scientific bodies and institutions in revolutionary Paris. Anyone working on Lamarck is necessarily limited by the almost total lack of biographical and personal material, but Burkhardt has gone carefully through the published writings and the manuscripts of Lamarck at the Musée d'Histoire naturelle, and those of Cuvier there and at the Institut. He has read widely in the literature of the period, and his sketches of the ideas and opinions of Daubenton, Faujas de Saint-Fond, Buffon, de Jussieu, Bruguière, and Lacépède, for example, are essential for understanding the variety of opinions and the wonderful richness of the biological, physical and chemical work in Paris in Lamarck's lifetime.

On Lamarck himself Burkhardt gives a useful sketch of his life and career, and the best analysis both of his evolutionary ideas and the way in which he altered his opinions, or at any rate some of them. The title of the book refers to that passion for system building (esprit de système) which had already been recognised as a major obstacle to scientific progress—Lamarck would not have liked its application to him at all, but it is justly used. He was a fanatical system-builder, far too hasty, far too impatient to test the validity of the 'facts' he built on, far too tenacious of dubiously correct ideas, and incredibly opposed to the best physical science of his day. He was, in short, a first-class

crank. One is reminded of Alfred Russel Wallace on anti-vaccination, life on Mars, spiritualism, land nationalisation, and the flat-earth people. Cranks are usually disastrously wrong, but when they are right, because of their fanaticism they are righter than most others—in some respects Wallace's *Darwinism*, which rather surprised Darwin, was better than the *Origin of Species*; and he was of course a great biogeographer. Lamarck also has plenty of claim to biological credit, for his taxonomic work; but his system of thought on the nature of life and on evolution reposed on such hopeless physical, chemical and geological foundations, and was presented with such disregard for scientific sobriety, that it is no wonder he was rejected by his contemporaries. One cannot but have sympathy with him for his unfortunate life, his blindness, his miserable last years; nevertheless, he was a crank. Burkhardt approaches him with too much deference to say anything of the sort, but he does indicate at the end that Lamarck cannot be considered a man ahead of his time.

Lamarck began his scientific work as a botanist, adept at constructing keys and fully aware of their artificial nature, believing in the immutability of species, and convinced that within the plant and the animal kingdoms separately there is a serial order which is the natural order. He knew well that both plants and animals vary considerably, often in relation to different climatic or cultural circumstances. He knew, as did everyone, that there was a balance in nature, such that all species continue, acting as checks on each other by predation; none, he believed, were lost. Two of these ideas, somewhat battered, he clung to to the end of his life—that within animals or plants there was a single natural serial order, or perhaps two; and that except for some large animals perhaps extinguished by man and the hordes of infusorians which could be easily destroyed by variations in external conditions, no extinction had taken place. It was this last conviction that, as Burkhardt shows very clearly, drove him to the idea of mutability of species—if it could not be that large numbers of species had become extinct, then they must have transformed into other species.

Right from the beginning, Lamarck had been thinking about the nature of plants, their constitution and physiology. He was especially impressed with the influence of climate, soils, and other environmental factors on them, and he started to think out a general theory of living and non-living things. It would be fascinating to look at his Jesuit schooling, which might

Cuvier

in part explain some of his ideas in physics and chemistry. He clung all his life to a thoroughly idiosyncratic four-element theory (of earth, air, fire and water) combined with those subtle and invisible fluids, magnetism, electricity, and so on, which were the common property of almost all scientists in the eighteenth century. At first he thought of the origin of the world, and the nature of motion and of life as wholly mysterious, but before he finished he could explain the powers of life entirely in terms of his own physics and chemistry. He also believed that matter without the action of life had no tendency to form compounds. Complex matter left to itself would continue to disintegrate, and he produced a degenerative series beginning with excretions, secretions and corpses, ending with the purest of all solid matter, rock crystal. Burkhardt considers the well-known antagonism between Cuvier and Lamarck to be a consequence perhaps of the former's religious views but also because he had a philosophy of stability antagonistic to Lamarck's ideas of change. It is as likely that Cuvier was a better scientist than Lamarck and that his ideas were better founded in the practical science of the period.

Lamarck's observations in geology had convinced him that the Earth had undergone very long slow gradual changes; he was an ultra-uniformitarian and therefore could think of no mechanism for large-scale extinction. He was also a good conchologist, and Burkhardt brings out well the importance of this subject for problems of extinction at the time—Faujas de Saint-Fond, struggling with it, was so eager for Lamarck's conchological system that he worked from the proofs of it. On the one hand, many species seemed to be extinct but to be related fairly closely to present ones; on the other, forms thought to be extinct occasionally turned up alive (a trigoniid claim in Australian waters, for example); and vast areas of the world were still unexplored. It was a difficult question, more so for Lamarck because large numbers of intermediate forms, which should have existed on his theory, had not come to light. Why he should have clung so tightly to non-extinction is not explained. I suspect it was because, as an ardent Deist he could not contemplate serious imperfection in the world. His over-riding faith, that everything happens by law, surely springs from this attitude and from the gigantic success of Newton. Probably, his belief that the time was ripe for a synthesis of all biology from the facts then available came from an unfortunate hint of Newton's that also influenced Erasmus Darwin deeply.

Once convinced that transmutation of species must have occurred, Lamarck immediately found a dual mechanism for it, a purely physico-chemical system, whereby life, once started in simple specks of matter, would through the circulation of fluids cause expansion, then channels for the fluids, then further complexities of organisation. This, by itself, would produce a uniform series of living things beginning daily with spontaneously arising animalcules, and ending after an incredible period of time with Man, the most perfect of all. But each animal, or plant, has to live in particular ways, and their circumstances would act to modify them for their roles. This would explain neatly why there is, ac-

cording to Lamarck but not Cuvier, an overall progression in the great groups of animals or plants but much difficulty in making serial arrangements of species or genera within them. This mechanism of adaptation was again a commonplace of the time, the inheritance of acquired characters. Lamarck said explicitly that he prided himself not on this mechanism but on seeing its enormous implications, which no-one else had done.

Lamarck had no reputation in France until it was necessary to find a national rejoinder to Darwin. Much of what was then written was uncritical in the extreme. Since about 1950, many excellent papers have appeared in various languages, and one can now hope to look at the natural history of Lamarck himself. This book is a major contribution, but it suffers somewhat, like so much written recently by historians and philosophers, from a lack of biology. For example, Burkhardt says that Lamarck's theory of evolutionary change was a specially eighteenth-century one, seen also in

Adam Smith, Hume, or Rousseau, in which a natural process takes place, but it is affected by constraining circumstances. The implication is that he was a child of his time, which in general is certainly true. But nevertheless he and all other biologists knew that the embryo in the uterus develops and complicates enormously in a nearly constant environment; there must therefore be a power of development independent of environmental fluctuations. He knew also that plants and animals when domesticated might change surprisingly; there must therefore also be a power of the environment over the results of development. It is difficult to see why this is a specially eighteenth-century interpretation.

Equally, there are moments when one wonders whether the author appreciates what Lamarck is referring to. Burkhardt mentions Lamarck's pointing out that "the isochronous movements of the large, soft radiarians" is like the movement of the liquid in a heated thermoscope. What Lamarck is referring to is simply the pulsations (as they swim) of big jellyfish, which will be familiar to most readers. Burkhardt stresses the importance of conchology, but does not give us any insight into what it means to Lamarck in his daily work and thought, apart from the example of the trigoniid already mentioned. Too much history of biology written by historians and philosophers omits too much of the biology. A history of ideas is good in itself, but in science, as against philosophy, those ideas have a practical context within the subject matter of that science which cannot be ignored. We have been shown far too often how scientists are the creatures of their times (which is true) and far too seldom how they are also influenced by their subjects. One possible source for Lamarck's ideas of fluids circulating and 'forming' vessels for themselves might be found in the teratological and embryological knowledge of the period.

The book is exceptionally well written, with only a few infelicities of translation (brute matter is not a good translation of *matière brut*, and conscience in French is not conscience in English) or idiom (no-one did anything in 1797, only *as of* it, an unnecessary pseudolegalism) or checking (notes 88 and 89, chapter 5, and note 1, chapter 6 are incorrect references according to my copies of Lamarck). It will be an indispensable introduction to the subject, and the basis on which an examination of Lamarck's actual biological knowledge can be reared. □

# Homo exquisitus

R. D. Meikle

*Ehret: Flower Painter Extraordinary.*  
By Gerta Calmann. Pp. 160. (Phaidon:  
Oxford, 1977.) £16.

THE history of Georg Dionysius Ehret (1708–1770) exemplifies the plight of many a botanical artist, dismissed (until recently) as a technician by the world of Art, and used, but scarcely appreciated, by botanists, to whom such elegant work seems to be of little more than peripheral importance.

Ehret was born in Heidelberg (or possibly Erfurt), the son of a gardener, with no advantages of birth save an observant eye and a natural talent for drawing and painting flowers. After a brief apprenticeship in horticulture, he turned to botanical illustration, serving a succession of patrons, who, it would seem, were rather more anxious to exploit his genius than to reward it. In many ways, his life resembles that of Mozart: plenty of appreciation, and no lack of hospitality, but probably always an acute shortage of cash. Like Mozart, his strivings for a measure of independence were labelled giddiness by his betters: "he is homo exquisitus in everything, he has only one fault, he is flighty".

His end was not a tragic one, perhaps because he had the good sense to head for England, where in time he became something of a celebrity, commending himself to Mrs Delany and the Duchess of Portland, and no doubt discovering that nothing is more acceptable to the English than an imperfect command of their language; for, even after thirty years' residence, he could barely make himself understood. In view of his reputed flightiness, even the daunting task of teaching the daughters of the nobility how to draw and paint flowers may have had its rewarding moments.

From his arrival in England, in 1736, until his death thirty-four years later, Ehret's life seems to have been tolerably pleasant, and was certainly very productive. It was not, however, the sort of life that was likely to contribute to his lasting fame. Much of his best work remained unpublished. Splendid paintings on paper and vellum may have given momentary gratification to the proud owners of stoves and exotica, but they were soon filed away and forgotten. The published engravings, even those in Linnaeus's *Hortus*

*Cliffortianus* and his own *Plantae et Papiliones Rariores* can scarcely be judged more than competent, whereas those in Trew's *Plantae Selectae* and *Hortus Nitidissimus* are sometimes mere travesties of the originals, almost as lifeless as the text which they accompany. Furthermore, the very works which Ehret illustrated ceased to be of more than scholarly and historic interest once the simple binomial system of plant nomenclature had been fully grasped.

Ehret was the contemporary (and avowedly the friend) of Linnaeus, but, in company with many of his patrons, he failed to appreciate the Linnean revolution in plant-naming, and continued to cling to "pre-Linnean" phrase-names long after the publication of the *Species Plantarum* (1753). It is for this reason that the writings of Miller, Aiton and even the ingenious Hill are still valued, whereas those of Trew and Weinmann were outmoded almost as soon as they left the press. Had it not been for the recent revival of interest in Ehret as an artist, there can be little doubt that his eclipse would have been total. In the unsympathetic world of taxonomy, he is, even now, little more than a penumbra.

Dr Gerta Calmann's monograph should dispel some of the shadows. But Ehret is a difficult person to write about. He was forever on the move, flitting, like one of his butterflies, from flower to flower and from patron to patron, without leaving any record of his activities save numerous signed and dated pictures and a brief autobiographical sketch specially designed to ease his entry into the Imperial German Academy of Naturalists. To make sense of such a complex and disjointed career, it is necessary to plan carefully and prune rigorously. Unfortunately,

Dr Calmann seems to have caught some of the flightiness from her subject. The text is widely informative, and often entertaining, but however much one may be amused by the antics of the Marcgrave of Baden-Durlach and his troop of female hussars, these, and similar digressions, do not help to concentrate one's mind on the essentials. Moreover, the author's frank admission that she is not a botanist does not excuse the astonishing string of errors on p48. Here, we are told that, "In a flash of insight Linnaeus realised that stamens and pistils were the sexual organs of plants", that his "artificial" system "was superseded finally by Darwin's theory of evolution", and that Linnaeus "created botanical Latin which simplified the identification of plants". Such *obiter dicta* do not necessarily impair the validity of the remaining text; but they undermine one's confidence.

The coloured illustrations, despite some, possibly unavoidable, reduction, are generally good, certainly very much better than many of the reproductions which appeared in Ehret's own lifetime. They have been selected to span almost the whole of his career; and although they do not demonstrate any remarkable development in skill or style, they do, fairly if rather unkindly, show the artist at his best and at his worst. His quality is certainly uneven, some of the plates, especially the Long-leaf Pine (pl.46) and the Christmas Rose (pl.95) being models of freshness and grace, whereas others, notably the Rose (pl.7) and more particularly the Poker-plant (pl.54) are so wooden and opaque that it is hard to believe they are by the same hand. The flattened, dive-bombing butterflies which appear in so many of his pictures are not, to my mind, an adornment; out of charity, one hopes they were forced on the artist to satisfy the catholic tastes of his naturalist patrons.

The monochromes are on the whole less satisfactory. Those which are allowed a full page are acceptable enough, though even here the "Characters of Flowers" (pl.75) with its amusing reminder of Ehret's faulty English, lacks much of the crisp quaintness of the original. The quarter- and half-page monochromes lose so much through reduction and absence of colour that one wonders if their replacement by a few additional colour plates would not have been wiser. The obscurity of one of these little illustrations (pl.16) may explain the misidentification of Thorow-wax (*Bupleurum rotundifolium*) as Yellow-wort (*Blackstonia perfoliata*). □

R. D. Meikle is on the staff of the Herbarium at the Royal Botanic Gardens, Kew, UK.

## South African cheer

K. L. Manchester

*A History of Scientific Endeavour in South Africa.* (A collection of essays published on the occasion of the Centenary of the Royal Society of South Africa.) Edited by A. C. Brown. Pp. 516. (Royal Society of South Africa, c/o University of Cape Town, 1977.)

ON 22 June 1877 in Cape Town was founded the South African Philosophical Society, which on 25 January 1908 by grant of Royal Charter from Edward VII became the Royal Society of South Africa. *A History of Scientific Endeavour in South Africa* has been written to commemorate the centenary of the Society, which is the oldest body of its kind in the country—probably in the African continent as a whole. Edited by A. C. Brown, Professor of Marine Biology at the University of Cape Town, the book consists of a series of historical essays by some of South Africa's leading scientists, recording the efforts of workers in many fields who have broadened knowledge and understanding of the South African habitat.

The Foreword by the State President describes the book as a tribute to the many who have contributed much of the basic knowledge and research that has made possible the transformation of South Africa from the remote and little-known land of hunters, pastoralists and subsistence agriculturalists it was in the seventeenth century to the economically advanced nation that has emerged in the twentieth—one of the world's leading producers of many minerals and the leading industrial nation in Africa. This may all sound a little like advertiser's copy, but as one of the contributors to the volume concludes: "It is doubtful whether many other countries can show a similar growth of scientific institutions and of the solid body of original work carried out by them, if one takes into account the size of the population."

Of course, South Africa has in some ways had things made for it. The enormous mineral deposits have been provided by Nature, even if exploited by man. The clear skies have attracted the astronomers and the wealth of wildlife the biologists. Not only is the wildlife extremely rich and varied but many of the species are endemic, due to the relative long isolation of parts of South Africa by desert from the rest of the continent. It is interesting to read that even in the early 1800s there was a

considerable demand for South African wild animals in Europe, and their export, both dead and alive, was a profitable business. Gone are the days when the springbok trekked over the Karoo in vast herds to the delight of the hunter. Wildlife conservation is rather better arranged today, and the game reserves of South Africa must rank amongst the best managed in the world.

More academically, in *Australopithecus africanus*, South Africa has fulfilled Darwin's prophecy that Africa would prove to be the home of the 'missing' link, and lately evidence of the presence of the more advanced *Homo habilis* has come to hand. The Karoo Formation is also remarkable for its wealth of unique fossil reptiles and the east coast waters for the coelacanth.

Inevitably, many of the chapters read like a catalogue of names and events which for the average reader will prove difficult to assimilate. Nonetheless it is impossible not to perceive the steady growth through the years of the various scientific disciplines from the incredibly primitive to the sophistication of the present day. The early settlers suffered grievous losses of crops and stock due to unfamiliar pests and disease. Pains-taking veterinary and agricultural research has overcome many of these problems, vastly extending the extent of habitable country. Institutions such as Onderstepoort, built up by the redoubtable Theiler, have a worldwide reputation.

Proper medical education in South Africa only began in 1912. Yet today, the Medical Schools of Cape Town and the University of the Witwatersrand stand amongst the best. *Xenopus laevis*, the South African clawed toad, has made its mark in modern molecular biology; but to a wider public the discovery in Cape Town in 1933 that *Xenopus* could be used for a bioassay for human pregnancy has possibly been of greater significance.

The exploitation of mineral resources naturally has stimulated engineering and metallurgical research. Rockbursts have to be understood if they are to be avoided. Pursuit of the gold bearing reefs to ever increasing depths has given South Africa unique experience of the engineering problems of deep level mining and the health hazards involved. Mining is a great consumer of energy, but South Africa is blessed with 60% or more of all African coal resources; and neighbouring territories have considerable hydroelectrical potential. We may no longer dream of a Cape to Cairo rail link, but electrical reticulation of southern Africa is today of considerable logistic significance. Lack of oil is the Achilles heel of the South African economy. In the SASOL

Advanced Publishing Programme:

**The Origin & Early  
Evolution of Animals**  
by Earl D Hanson

This major work presents a fresh approach to phylogeny, the major unfinished task in biological studies. Part I develops a consistent and rigorous set of phylogenetic principles; Part II applies them to the evolution of the unicellular and the more primitive multicellular animals; and Part III offers a critical overview of the theory and the phylogenetic conclusions which it generates. Earl D Hanson is Fisk Professor of Natural Science and Professor of Biology at Wesleyan University, Middletown, Connecticut.

RECENT PUBLICATIONS

**STRUCTURE AND FUNCTION OF  
HAEMOCYANIN**

Editor: J.V. Bannister

194 figures, 54 tables, 310 pages Cloth DM 76  
ISBN 3-540-08284-0 (Approx. £19.)

This volume contains the proceedings of an International Workshop held at the Marine Biological Laboratory of the University of Malta. The Workshop, sponsored by the European Molecular Biology Organization and the University of Malta, concerned the study of the structure and function of Haemocyanin. It was the fifth of such a series of meetings organized on haemocyanin. Current information on haemocyanin as a protein and as an oxygen carrier were discussed and form the main contents of this volume. The proceedings of the first meeting on haemocyanin held at Naples about 10 years ago were also published and it is interesting to verify that the study of this protein has really been stimulated since that time. Novel techniques such as NMR and EPR have been introduced, the kinetics of oxygen binding by the protein has been expanded and much more is known about the subunit assembly.

**ADVANCED METHODS IN PROTEIN  
SEQUENCE DETERMINATION**  
(Molecular Biology, Biochemistry and  
Biophysics Vol. 25)

Editor: S.B. Needleman

96 figures, 25 tables, 200 pages Cloth DM 56  
ISBN 3-540-08368-5 (Approx. £14)

The determination of protein sequences has become so commonplace that laboratories, only a few years ago unable or unwilling to undertake such studies because of the "sophisticated" procedures involved, today perform them as a routine part of their overall research programs. However, as more laboratories have entered this area of study, the sophistication of the technology has, in fact, progressed to make use of physical properties not previously utilized for this purpose. Earlier manual techniques have become automated; current instrumentation operates at higher parameters and with greater precision than before. Thus the present volume supplements the earlier one in presenting details of the more advanced technologies (optical, high pressure, X-ray, immunologic etc.) being used in sequence determination today.

**OPHIOLITES (Minerals and Rocks Vol. 12)**  
Ancient Oceanic Lithosphere  
R.G. Coleman

72 figures, 18 tables, 240 pages Cloth DM68  
ISBN 3-540-08276-X (Approx. £17)

This book consolidates our knowledge on ophiolites, which have recently been shown to play an important role in the new plate tectonic hypothesis. They represent fragments of ancient oceanic lithosphere and their tectonic setting and age are extremely important in the reconstruction of ancient plate boundaries and the formation of ancient oceanic crust. Emphasis is on the igneous petrology of these rocks and the magnetic processes leading to the association of submarine basalts, diabase, mafic-ultramafic cumulates, and tectonized peridotites.

ICN-UCLA SYMPOSIA ON MOLECULAR AND CELLULAR BIOLOGY, VOLUME VI

## REGULATORY GENETICS OF THE IMMUNE SYSTEM

Edited by ELI S. SERCARZ, LEONARD A. HERZENBERG AND C. FRED FOX

CONTENTS: I. GENE STRUCTURE AND ORGANIZATION. Transcriptional and Translational Control. Inheritance and Expression of Ig Genes. II. IDIOTYPES ON T AND B CELLS. Receptors and Recognition. Idiotypic Control of Immune Responsiveness. III. LYMPHOCYTE SUBPOPULATIONS AND GENES DETERMINING SURFACE STRUCTURES. Expression of I-Region Markers and Other Non-Ig Markers. B and T Cell Surface Immunoglobulin. IV.

GENETICS OF CELL INTERACTIONS. Gene Products Involved in I-Region Regulation. Restrictions in Cell Interactions. Immune Response Genes and Their Mechanisms of Action. Mechanisms of Suppressor-Helper T-Cell Control. V. MHC and T-CELL RECOGNITION. VI. THE MEMBRANE AND CELL ACTIVATION.

1977, 784 pp., \$29.50/£20.95 ISBN: 0-12-637160-1

ICN-UCLA SYMPOSIA ON MOLECULAR AND CELLULAR BIOLOGY, VOLUME VII

## MOLECULAR HUMAN CYTOGENETICS

Edited by ROBERT S. SPARKES, DAVID E. COMINGS AND C. FRED FOX

From the Preface . . .

Recent years have seen very rapid progress in cytogenetics. Many of the advances have been at the molecular level and this accounts for the focus of the present conference. Knowledge and advances in all areas of genetics have implications for human genetics; it thus seemed desirable to bring human cytogeneticists together with scientists active in basic genetics research on other species. The desire to create a mutual awareness of the current status and problems faced by human cytogeneticists and geneticists working in nonhuman

systems was gratifyingly achieved by the participants in the conference. Most of the plenary papers and some of the poster sessions presented at the meeting are included in this volume.

SECTION HEADINGS: I. Chromatin Structure. II. Chromosome Structure. III. Chromosome Mapping. IV. The X and Y Chromosomes. V. Sister Chromatid Exchange. VI. Cytogenetic Evolution. VII. Clinical Cytogenetics.

1977, 472 pp., \$19.00/£13.50 ISBN: 0-12-656350-0

ICN-UCLA SYMPOSIA ON MOLECULAR AND CELLULAR BIOLOGY, VOLUME VIII

## MOLECULAR APPROACHES TO EUKARYOTIC GENETIC SYSTEMS

Edited by GARY WILCOX, JOHN ABELSON AND C. FRED FOX

This important compendium of papers describes new methods and approaches of molecular biologists who have pioneered and are using the techniques of recombinant DNA research and rapid DNA sequencing, and of geneticists who have established promising eukaryotic genetic systems. The book contains the proceedings of the ICN-UCLA symposium on "Molecular Approaches to Eukaryotic Genetic Systems" which was held in Park City, Utah from February 27 to March 4, 1977. The meeting was highly participatory, and the volume, reflecting

this fact, includes plenary papers, selected papers from the poster sessions, and summaries of the workshops.

CONTENTS: I. Rapid DNA Sequencing Techniques. II. Recombination DNA Technology: Methods and Results. III. Genetics and Molecular Biology of Yeast. IV. Genetics and Molecular Biology of Neurospora and Slime Molds. VI. Genetics and Developmental Mechanisms in Nematodes. VII. Mammalian Genetic Systems.

1977, 448 pp., \$19.50/£13.85 ISBN: 0-12-751550-X

## THE ATLAS OF INSECT AND PLANT VIRUSES:

INCLUDING MYCOPLASMAVIRUSES AND VIROIDS

Edited by KARL MARAMOROSCH

A Volume in the ULTRASTRUCTURE IN BIOLOGICAL SYSTEMS Series

From the Preface . . .

"The Atlas of Insect and Plant Viruses" is a companion volume to "Ultrastructure of Animal Viruses and Bacteriophages: An Atlas," edited by Dr. Albert J. Dalton and Dr. Francoise Haguenau, published by Academic Press in 1973. It includes a description of viruses infecting insects, higher plants, fungi, mycoplasmas, and spiroplasmas. The smallest recognized disease agents, viroids, have also been included, although they are not classified as viruses. The contributors have presented the

information available on the ultrastructural aspects of viral replication and the organization of the virion in the diverse groups.

SECTION HEADINGS: PART I. Insect Viruses. PART II. Plant Viruses. PART III. Mycoviruses and Viroids. PART IV. Mycoplasma and Spiroplasmaviruses.

1977, 512 pp., \$49.50/£35.15 ISBN: 0-12-470275-9

**CURRENT TOPICS IN DEVELOPMENTAL BIOLOGY, VOLUME 11****PATTERN DEVELOPMENT**

Edited by A. A. MOSCONA and ALBERTO MONROY

CONTENTS: S. B. Oppenheimer, Interactions of Lectins with Embryonic Cell Surfaces. A. Gierer, Biological Features and Physical Concepts of Pattern Formation Exemplified by Hydra. J. P. Merlie et al., Molecular Aspects of Myogenesis. P. D. Nieuwkoop, Origin and Establishment of Embryonic Polar Axes in Amphibian Develop-

ment. J. Brachet, An Old Enigma: The Gray Crescent of Amphibian Eggs. D. L. Rayle and R. Cleland, Control of Plant Cell Enlargement by Hydrogen Ions. (The above contents are tentative.)

1977, 224 pp., \$19.50/£13.85 ISBN: 0-12-153111-2

**SEARCH AND DISCOVERY****A TRIBUTE TO ALBERT SZENT-GYORGYI**

Edited by BENJAMIN KAMINER

This volume is dedicated to Albert Szent-Györgyi and stems from a symposium, "Search and Discovery," held in his honor at Boston University School of Medicine. The contributors are leading researchers in their respective fields, and five are Nobel Laureates. The papers encompass the fields of Szent-Györgyi's major contributions and interests: metabolism, vitamin C, molecular mecha-

nisms and control of muscle contraction, molecular and submolecular biology, cell growth, and cancer, as well as the interrelationship of science and society.

SECTION HEADINGS: Metabolism. Vitamin C and Health. Muscle. Cross-Linking and Complexes. Submolecular Biology. Cell Growth and Cancer.

1977, 368 pp., \$21.50/£15.25 ISBN: 0-12-395150-X

**PROGRESS IN ACETABULARIA RESEARCH**

Edited by C. L. F. WOODCOCK

FROM THE PREFACE:

The Fourth Meeting of the International Research Group on Acetabularia was held on the Amherst Campus of the University of Massachusetts in September 1976. . . . This symposium was the latest in a series of biennial meetings and reflects the continued need for close communication between investigators using Acetabularia as a research organism.

SECTION HEADINGS: Genetics and Information Processing. Enzymes and Biosynthetic Pathways. Chloroplasts. Growth and Morphogenesis. Methodology.

1977, 358 pp., \$18.00/£12.80 ISBN: 0-12-763750-8

**LYMPHOCYTE DIFFERENTIATION, RECOGNITION AND REGULATION**

By DAVID H. KATZ

A Volume in IMMUNOLOGY: An International Series of Monographs and Treatises

CONTENTS: Introduction. Surface Antigens and Markers on T Lymphocytes. Surface Antigens and Markers on B Lymphocytes. Surface Antigens Present on T Lymphocytes and Also on B Lymphocytes. Ontogeny of the Two Major Classes of Lymphocytes. Surface Immunoglobulin on Lymphocytes. Immunological Specificity of Immunocompetent Lymphocytes. Functional Properties of T Lympho-

cytes. Functional Properties of B Lymphocytes. Regulatory Cellular Interactions in Immune Responses. The Allo-genetic Effect on Immune Responses. Genetic Control of Immune Responses and Cellular Interactions. Mechanisms of Regulatory Cellular Interactions. Immunological Tolerance. Concluding Remarks.

1977, 720 pp., \$42.00/£29.80 ISBN: 0-12-401640-5

**A BIOCHEMICAL PHYLOGENY OF THE PROTISTS**

By MARK A. RAGAN and DAVID J. CHAPMAN

A *Biochemical Phylogeny of the Protists* examines the biochemist's contributions to phylogenetic research. Focusing on the protists—a biochemically diverse and inadequately studied group of organisms—the authors examine how fundamental progress in biochemistry and molecular biology has brought a new, biosynthetically based approach to phylogenetics. They indicate biochemical characters which have been useful in construct-

ing phylogenies, and explore the underlying bases of this usefulness. In addition, areas likely to be most rewarding for future phylogenetic research are specified. Special emphasis is given throughout to the phylogeny of higher taxa of eukaryotic algae and to fungi, but bacteria and protozoa are treated whenever possible.

1977, 320 pp., \$29.50/£20.95 ISBN: 0-12-575550-3

**ECOPHYSIOLOGY OF TROPICAL CROPS**

Edited by PAULO de T. ALVIM and T. T. KOZLOWSKI

This book defines the ecological requirements of the major tropical crop plants and examines the effects of environmental and cultural practices on growth and yield through the intermediation of physiological processes. The subject matter comprises plant physiology, plant ecology, agronomy, horticulture, meteorology, and soil science.

The volume brings together the present state of knowledge on the physiological and ecological principles un-

derlying the relationships between environment and crop production in the tropics. It comprises 18 chapters by leading researchers on tropical climate and soils as well as case history reviews of the ecophysiology of the major crop plants, including rice, sugar cane, pineapple, grasslands, sweet potato, coffee, cacao, rubber, tea, oil palm, coconut, citrus, banana, cashew, and mango.

# Prentice/Hall International

66 Wood Lane End Hemel Hempstead, Herts. HP2 4RG

As one of the world's leading educational and scientific publishers, we are pleased to announce these new and forthcoming titles in **Computer Science, Electrical Engineering, and Psychology**, some of the major areas covered in our extensive list for postgraduate and professional reading. Write for the catalogues of your choice to Elaine Scribens at Prentice-Hall International.

**Computer Methods for  
Mathematical Computations**  
**G. E. Forsythe, M.A., Malcolm and  
G. B. Moler**

An innovative text on numerical methods used in scientific computation, this highlights ten FORTRAN sub-routines for the computer solution of mathematical problems. These involve matrices, integrals, zeros and extrema of functions, least squares, and Monte Carlo techniques. Exercises can be applied to problems in physics, engineering, ecology and statistics.

**1977 c.304pp £12.75**

**The Architecture of Concurrent Programs**  
**Per Brinch Hansen**

Presents a systematic method for developing reliable, concurrent programs in a structured language. It includes the complete program text of three mini-computer systems and explains how they are structured, programmed and tested.

**December 1977 328pp £13.55**

**Digital Image Restoration**  
**H. S. Andrews and B. R. Hunt**

'Gives a vivid idea of what is happening in computer image processing and of the directions that the subject is likely to take in the near future. . . It is clear and carefully organised; the numerous pitfalls and still unsolved problems are signposted; the notation is easily readable.' - *Nature*, 21 July.

**1977 238pp £19.95**

**Applications of Digital Signal Processing**  
**Alan V. Oppenheim**

A 'state-of-the-art' discussion by an international group of contributors who review digital signal processing in a wide range of applications, such as telecommunications, speech and image processing, radar and geophysics.

**March 1978 464pp £18.40**

**Cognitive Psychology**  
**Allan G. Reynolds and Paul W. Flagg**

The unfolding developments in the study of how we think and perceive are admirably covered, drawing on post-war contributions from computer science, information theory and linguistics.

**1977 457pp £11.95**

**Associative Learning:**  
**A Cognitive Analysis**

**J. G. Greeno, C. T. James, F. DaPolito  
and P. G. Polson**

An alternative argument to the associationist thesis, this new work applies concepts of storage and retrieval of relational information to our understanding of associative learning.

**1978 c.256pp £11.15**

**Psychopharmacology in the Practice  
of Medicine**

**Murray E. Jarvik**

A primer of interest to psychiatrists and clinical psychologists, this covers psychopharmacology in the practice of medicine; experimental psychopharmacology; clinical psychopharmacology (in which the rationale for drug treatment is presented); as well as a section on drugs of dependence. **1977 553pp £16.40**

**Image Formation and Cognition/2E**

**Mardi J. Horowitz**

Summarises visual imagery experiences and all their dimensions, ranging from hallucinations to everyday thought images, from dreams to common memories. After giving a clear description of the variety of mental images, and the circumstances that increase imagery, the book goes on to deal with all the psychological and neurobiological factors that influence image formation. **1978 c.400pp £15.15**

Circle No. 20 on Reader Enquiry Card.

coal to oil process the country seeks self-sufficiency both for oil and petrochemicals.

A final chapter is devoted to the history of the Royal Society itself. It is amusing to find that in 1902 and 1905 the Society made a strong case for metrication of weights, measures and coinage in South Africa, an attempt that failed due to pressure exerted in the British Parliament. The Society was 60 years too early.

It is impossible to summarise in any meaningful way the mass of detailed material contained in this volume. To

anyone with an interest in South Africa or in the historical concept of how a country can develop scientifically the book is a must. The Royal Society of South Africa is to be congratulated in seeking to put together for the first time the fascinating story of the growth and discoveries of science in southern Africa. Into an atmosphere of political gloom and frustration it injects a note of human achievement and cheer. □

## Historical revisionism

M. J. S. Rudwick

*The Making of Geology: Earth Science in Britain, 1660–1815.* By Roy Porter. Pp. 288 (Cambridge University: London, Cambridge and New York, 1977.) £8.95.

MOST Earth scientists are conscious of the great conceptual integration that plate tectonic theory has brought to their science in the past two decades. In retrospect, the immediately preceding period seems like a time of relative stagnation or, at best, of several disparate disciplines evolving in relative isolation.

This situation is not unlike an earlier period, to which historically conscious geologists often look back to find the origins of Earth science as a whole. In doing so, however, they generally adopt an historical interpretation that was itself a product of that period. The scientists who first gave 'geology' its institutional and cognitive identity in the early nineteenth century looked back to the eighteenth and late seventeenth centuries as a period of benighted obscurantism or fanciful speculation, relieved only by a few isolated

pioneers or forerunners of their own approach.

This is the interpretation that Dr Porter has set out to demythologise. His book is a conscious piece of historical revisionism, yet in no sense is it a facile exercise in debunking. His starting point is the striking discrepancy between the negative evaluation that nineteenth-century geologists gave to the work of their predecessors, and the actual content and scope of that work. The latter is reconstructed by historical analysis of an impressive array of published books and articles, unpublished field notebooks and correspondence, and other material, illustrated by often fascinating quotations. Dr Porter suggests, in my opinion persuasively, that early nineteenth-century geologists rejected or disowned the past history of their subject, because they felt they had successfully constructed a self-sustaining social enterprise with a new research programme of unlimited potentialities—significantly, the very word 'geology' only came into general use at that time. They contrasted this with the relatively undirected and even confused activities of their predecessors. Failing to see how these activities had been an indispensable precondition for their own work, they exaggerated the contrast into an almost total discontinuity.

*Making* is the key word in Dr Porter's title and in his interpretation.

Although the Earth was in an obvious sense always 'there' to be studied, the body of theoretical ideas and practical techniques that characterised the new science of geology was constructed out of the choices and decisions of individuals and groups in specific historical circumstances. To put it another way, the manifest heuristic success and cumulative character of the mature science of geology since the early nineteenth century is a historical phenomenon that calls for explanation, just as much as the 'failure' of earlier generations to create such a self-sustaining enterprise.

Dr Porter's approach is one in which the traditional dichotomy between 'internalist' and 'externalist' history of science is shown up in all its sterility. It is pointless to trace the growth of a community of like-minded 'geologists', or the reasons why that group developed when and how it did, without analysing the theories and techniques to which their likemindedness was directed; but the converse—the style of traditional 'internalist' history of science—is equally futile. Dr Porter succeeds admirably in blending context and content into a single integrated interpretation.

This book is not, and does not claim to be, a definitive or exhaustive description of all the research that was carried out during the period 1660–1815, even within Britain. It is a suggestive outline of a new way of looking at the early history of the earth sciences. The first appearance of a self-conscious science of geology is not seen as a product of an intrinsic progressiveness of knowledge or of the genius of a few pioneers—interestingly, the Scottish natural philosopher, James Hutton, still sometimes called 'the founder of modern geology', is shown to have been somewhat isolated from the mainstream development of the science. Instead, the emphasis is on the purposeful construction of an integrated discipline with clearly defined methods and—at first—quite narrowly limited cognitive aims; and this construction is seen as the work of individuals and groups working in specific circumstances that constrained the social forms in which their activity was embodied.

The geology that had thus been 'made' by the early nineteenth century is recognisably continuous with the earth science of today, even after its most recent 'revolution'. Dr Porter's account of this construction can be warmly recommended to all Earth scientists who are interested in the foundations of their science. □

# Philosophical conflict

Peter Winch

*Wittgenstein and Scientific Knowledge: A Sociological Perspective.* By Derek L. Phillips. Pp. 248 (Macmillan: London, 1977.) £10.

THE aim of Professor Phillips' book is to bring Ludwig Wittgenstein's philosophical work to the attention of sociologists, in the belief that it has something to contribute to issues which exercise them. It is concerned mainly with certain issues in the general philosophy of science which have recently come to the fore in the conflict between the hitherto dominant positivist and Popperian conceptions of science and the work of such writers as Thomas Kuhn and Paul Feyerabend. These issues touch the work of sociologists most directly in the area of 'sociology of knowledge', stemming from Karl Mannheim. As Phillips observes and brings out, many of Wittgenstein's ideas are very germane to such issues: particularly, the notes he wrote towards the end of his life published in *On Certainty*. The two issues in the philosophy of science and sociology of knowledge on which the book under review focusses most directly are: (1) relativism and the claim, arising especially out of Kuhn's work, that theories separated by a 'scientific revolution' are incommensurable; (2) where does authority lie in science: who, that is, decides what is respectable science and what isn't? Phillips has interesting things to say about both these topics, especially the first, though his treatments of them are not entirely consistent with each other. But I shall return to this point later.

The structure of the book is loose and not altogether perspicuous. There are chapters which are exclusively expository of some of Wittgenstein's main philosophical ideas; chapters in which some of these ideas are brought to bear directly on those issues in the sociology of knowledge in which Phillips is most interested; a chapter in which those issues are treated without explicit reference to the relevance of Wittgenstein's work to them. Overall, this gives an impression of disjointedness: the various issues discussed do indeed have important interconnections, but they are too often presented in indigestible chunks, and not enough work has been done to work them into a coherent whole. This is especially true of the

relationship between the first chapter on 'Wittgenstein the Man' and the exposition of his philosophy.

Phillips touches on an important and difficult tangle of problems when he claims that there is an "intimate link between [Wittgenstein's] life and his work", but he does not really attempt to clarify them. He relies very uncritically on sources concerning Wittgenstein's life which are less than impressive, such as W. W. Bartley III's *Wittgenstein*, some of whose extravagant claims are accepted as gospel, without any allusion to the surely justified doubts of many reviewers of that book about the quality of the evidence adduced in support of those claims. More importantly perhaps, he shows no signs of having reflected on any of the really puzzling questions about the relationship between a man's life and his work of the sort raised for instance, by Rush Rhees in his discussion of Bartley's book in *The Human World*. Yet those questions, one might think, have a direct bearing on the issues in the 'sociology of knowledge' which are at the centre of Phillips' interest.

I am not sure how useful the very compressed account of Wittgenstein's early and later philosophy will be to those to whom it is addressed. I doubt if it will be very intelligible to people who are not already pretty familiar with the issues involved and, though the presentation is superficially lucid, there are a number of more or less serious examples of carelessness of which the following are just examples. On page 30 it is said that, according to Wittgenstein's *Philosophical Investigations*, "Nothing exists outside of our language and actions which can be used to justify, for example, a statement's

truth or falsity". It is true that Wittgenstein opposed the view that there need or could be an "external" justification of the grammar of our language; and also that he thought this grammar required a certain "agreement in judgements"; but this does not mean that he denied the possibility of establishing the truth or falsity of any statement by reference to things which exist independently of us and our linguistic practices. Again, Phillips writes, on page 82, that according to Wittgenstein "it is a contingent fact that the concepts of pain and grief connect up with a certain uniformity of judgement among human beings". Clarity about what is contingent and what is not is of the essence in such issues: what Wittgenstein said is contingent is that there should exist the sort of "uniformity of judgement" among human beings which makes it possible for them to have concepts such as grief and pain; not that, given such uniformity of judgement, men's concepts of grief and pain connect up with it. I am afraid that slips of this sort, about quite fundamental issues, may seriously mislead the newcomers to Wittgenstein's philosophy to whom, I take it, the book is addressed.

Chapter 5 seems to me the best. It deals with claims about the incommensurability of scientific theories involving different "paradigms" arising out of the work of writers like Kuhn. Here, Phillips makes illuminating use of Wittgenstein's view that the language of scientific theorising has a continuing dependence on the language of everyday life; and he connects this usefully with Wittgenstein's discussion of the distinction between "seeing" and "seeing as" (or "seeing an aspect"). This chapter deserves attention by anyone interested in the questions surrounding the notion of incommensurability of theories. I hope readers will not be misled by Phillips' idiosyncratic use of the term "meta-language" in speaking of the relationship between the language of everyday life and the languages of the sciences. His conception has nothing in common with that expressed by the established technical use of "meta-language" amongst philosophers of language and logicians influenced by Tarski.

Chapter 7 has some useful material on the power structures of scientific institutions and their role in the "validation" of scientific theories. Phillips surely goes too far, however, when he claims that the individual scientist's "explanatory achievements are fully [my emphasis] dependent upon the judgements of the scientific community or the speciality area in which he works" (page 40). This would lead back

## THE REITH LECTURES

### **Mechanics of the Mind** COLIN BLAKEMORE

'... a remarkable tour de force, a masterpiece of brief intelligent exposition of a complicated and technical subject, part history, part science, part philosophy.'

*The Times*

'... an excellent introduction for the general reader to contemporary brain research in its various aspects ...'

*The Observer*

**Hard covers £10.50 net**  
**Paperback £3.95 net**

*Paperback edition*

### **The Force of Knowledge**

#### **The Scientific Dimension of Society** JOHN ZIMAN

'... one of the best undergraduate-level introductions to the social relations of science I have read.'

*Sociology*

'... a highly informative and provoking book that can with profit be studied by all university teachers of science and their students ...'

*New Scientist*

*Also available in hard covers*

**Paperback £4.75 net**

### **The Pursuit of Nature**

#### **Informal Essays on the History of Physiology**

A. L. HODGKIN, A. F. HUXLEY, W. FELDBERG,  
W. A. H. RUSHTON, R. A. GREGORY  
and R. A. McCANCE

A collection of essays, written as part of the celebrations of the Centenary of the Physiological Society.

'The delightful blend of scientific and personal anecdote captures the spirit of the society in its more relaxed moments.'

*New Scientist*

**£7.50 net**

*Paperback edition*

### **Introduction to Fungi** JOHN WEBSTER

A clearly written account of the fungi based on the taxonomic division proposed by Ainsworth in 1966. A major feature of the book is the many photographs and drawings and it will be of interest not only to undergraduate students of botany but also to anyone with an interest in this fascinating subject.

*Also available in hard covers*

**Paperback £4.95 net**

### **The Making of Geology**

#### **Earth Science in Britain 1660-1815** ROY PORTER

Between the mid-seventeenth century and the early nineteenth century there developed in Britain a range of empirical and increasingly secular sciences concerned with the Earth. This book presents the first detailed account of how this development led to the emergence of 'geology' as an independent discipline.

**£8.95 net**

### **Illustrating BASIC**

#### **(a simple programming language)** DONALD ALCOCK

To make a computer do a calculation you must first describe every step of that calculation in a language the computer can understand. This book presents a popular and widely available language called BASIC and explains how to write simple programs in it. It is intended for all beginners and you do not have to be a computer scientist to read it.

**Hard covers £4.95 net**

**Paperback £1.90 net**

### **Celestial Masers**

#### A. H. COOK

This book summarises relevant molecular physics and gives a general account of the observations of maser sources and of the principles of the theory of maser action. Emphasis is placed on unsolved problems and the book will interest physicists, astronomers and astrophysicists at undergraduate, graduate and research levels.

*Cambridge Monographs on Physics*

**£7.50 net**

### **Liquid Crystals**

#### S. CHANDRASEKHAR

A systematic and self-contained treatment of the physics of the three types of liquid crystals — nematic, cholesteric and smectic — describing their structures, their thermodynamics, optical and mechanical properties and their behaviour under external fields.

*Cambridge Monographs on Physics*

**£18.00 net**

### **The Science and Practice of Welding** Seventh Edition

#### A. C. DAVIES

A comprehensive textbook on the basic theoretical principles underlying the various processes of welding and the practical methods of applying them. This edition has been extensively revised, added to and updated.

'... will probably continue to be used as an introductory textbook for some time yet.'

*Welding and Metal Fabrication*

**£7.00**

### **Abortion**

#### MALCOLM POTTS, PETER DIGGORY and JOHN PEEL

The first comprehensive account of abortion that deals with its history, sociology, clinical and demographic aspects and which faces the ethical issues involved. An important book that will be of interest not only to members of the medical and nursing professions but also to more general readers.

to the type of relativism which earlier chapters were designed to avoid; and Phillips here forgets his own correct contention that the technical languages spoken by "scientific communities" are not fully autonomous, but depend for their sense on a relationship to the non-

technical language used in the wider human community to which they belong. A particular scientific elite is not a court beyond which there is no appeal. □

Peter Winch is Professor of Philosophy at King's College, University of London, UK.

## Remote and legendary figure

Sydney Selwyn

*Joseph Lister, 1827-1912.* By Richard B. Fisher. Pp. 351+16 plates. (Macdonald and Jane's: London, 1977.) £7.95.

ON the 150th anniversary of his birth and a mere 65 years after his death, Joseph Lister has already become an extremely remote, almost legendary figure. Even in his lifetime, during the 40 years of fame when every conceivable honour came his way, Lister appeared aloof and enigmatic. Little or no insight into his personality can be gained from the only two full-length biographies available until now, that of G. T. Wrench published in 1913, and the official one by Lister's nephew, Sir Rickman Godlee, which first appeared in 1917. Happily, the new biography by Richard Fisher deals fully not only with Lister's varied scientific and surgical work, viewed from the perspective of our own time, but also with Lister the man. Drawing on a considerable volume of unpublished correspondence, diaries and laboratory notebooks, the author's portrait will reveal for most readers an unexpectedly complex individual. Certainly, the popular view of Lister as the serene benefactor of mankind whose work on antiseptic surgery was greeted with universal acclaim has long needed correction. A glance through the editorial and correspondence columns of the *Lancet* and *British Medical Journal* from 1867 into the 1880s shows Lister to be at the centre of polemics—many of his own making and not all concerned with antiseptic surgery.

Lister was fortunate in his background—a congenial quaker family originating in Yorkshire, quaker friends such as Thomas Hodgkin and Elizabeth Fry who were devoted to science and philanthropy, and a prosperous wine merchant father, Joseph Jackson Lister, who by 1830 had made fundamental contributions to microscopy and was to become a life-long mentor and confidant of his son. As a student Lister performed extremely well at University

College, London until 1847, when he underwent a religious crisis and in March 1848 suffered a severe 'nervous breakdown' of a depressive nature, which prevented any further work for 18 months. Although he eventually made a good recovery, Lister subsequently was afflicted by recurrent self-doubts and a type of paranoia. His biographer convincingly uses psychological analysis to explain the paradox of a man who was gentle, kind, chivalrous and in many ways noble, but who was often publicly tactless, obtuse and, for example, an implacable opponent of the entry of women into medicine. Fortunately, Lister's mar-

Lister at Glasgow in 1865

riage, though childless, was extremely happy. His wife (a non-quaker) was his constant support, amanuensis and laboratory assistant. Moreover, in the stormy early days when Lister was under frequent attack in the medical journals he had the consolation of regular support from the young journal *Nature*.

Lister's scientific work is, in general, well reviewed. The early studies on involuntary muscle, inflammation and blood coagulation earned him, at the age of 33, a Fellowship of the Royal Society—where he joined his father and was eventually a most distinguished President. Most of this work was primarily carried out to provide material for Lister's undergraduate lectures. Using the microscope perfected by his father, Lister over a

ten-year period made meticulous observations on various contractile tissues and on the effects of irritants on the microcirculation of the frog's foot web. He greatly clarified the early events in inflammation by describing, in sequence, arteriolar constriction, slowing of blood flow and increased adhesiveness of erythrocytes—the latter having been first observed *in vitro* by his father and Thomas Hodgkin in 1827. Simultaneous changes in the pigmentation of the foot web underlined for Lister the truth of John Hunter's belief that inflammation was an active process. Similarly, blood coagulation was also shown to be a series of processes governed by tissue and vascular factors and not due, as was widely believed, to the passive loss of a 'liquefier' such as blood ammonia.

Lister always held that this work was his major scientific contribution: bacteria, which were so prominent in his later work, were simply specific irritants that triggered off inflammation and, occasionally, intravascular coagulation. To most modern observers, however, his pioneer microbiological researches from 1868 until the mid-1880s seem far more important. They were not only crucial in the battle against abiogenesis, but provided much-needed scientific support for Lister's 'Antiseptic System', which was at first extremely vulnerable at the hands of informed opponents.

Adequate attention is given in the book to Lister's technical achievements, including his method of obtaining in 1877 a pure bacterial culture by serial dilution. But the author in discussing the complex early studies on bacteria and fungi misses the extraordinary fact that Lister observed the antibacterial action of *Penicillium* species in 1871, and later used crude penicillin preparations in treatment.

Unfortunately, the book contains many medical and medical historical solecisms. For instance, jaundice is not synonymous with hepatitis, pin-worms do not cause skin disease ('ringworm' does), hospital gangrene was not due to soil-borne bacteria, and hydrocele is not a testicular growth. William Harvey published in the seventeenth, not the sixteenth century; Sir James Simpson worked in Edinburgh, not Aberdeen; Ehrlich's great chemotherapeutic work was on arsenicals, not mercurials; and Behring was certainly not a colleague of Pasteur. Although these and other blunders are irritating, Mr Fisher has written a definitive biography of a remarkable man. Such a book has been long awaited and is to be warmly welcomed. □

Sydney Selwyn is Reader in Medical Microbiology at Westminster Medical School, London, UK.

# American Nobel elite

Steven Rose

*Scientific Elite: Nobel Laureates in the United States.* By Harriet Zuckerman. Pp. xv+335. (Free Press: New York; Collier-Macmillan: West Drayton, UK, 1977.) £11.25.

NOBEL PRIZES are news and not merely because the money is of the order of a middle-sized pools win. The awards make not only *The Times* but the BBC news and *The Mirror* as well. National statistics of Nobel Prize winners are counted anxiously as a measure of scientific health. The Prize is seen as the apotheosis of a scientist's career, and the equality of opportunity with which graduate scientists are supposed to start up the hierarchical ladder emphasises the myth that, like napoleonic field-m Marshals, the laurels are in every Ph.D. student's lab-coat.

Nobel Prize winners are the nearest equivalent in science to archbishops, or pop or movie stars (barring the age-differential, of course, so far as the latter are concerned). They are invited

to serve on government committees in-differently, more-or-less, to the actual subject-matter of their expertise; the media hang on their words; films and TV plays are made about them. They pronounce with authority on subjects as diverse as ethics and ecology, the limits of human intellect and of industrial growth.

No appeal for humanitarian causes, whether a paid advertisement in the western press or a smuggled *samizdat* letter, is complete without the mystic *imprimatur*. Clearly, the phenomenon of the laureate is one of some importance in understanding the social system of science, whether considered from the point of view of the internal 'community' of scientists themselves or its relationship to the wider social matrix within which it is embedded and which it helps shape.

For the sociologist, I would guess that the problem of the study of elite groups must be considerable. Their numbers are small and individuals easily identified so that generalisations are harder; they are likely to be less amenable to standard procedures of interview or questionnaire than the less illustrious subjects who generally form the core of sociological specimens, and this must put the researcher's relationship with his or her subjects on a different (more deferential?) footing. Also, the objects of one's survey are actually likely to read what one writes—and if they don't like it, they have their ways. . . . Perhaps it is for this reason that the poor are more often studied than the rich?

Despite these problems, some of which she discusses, Harriet Zuckerman has been attempting, since the early 1960s, a dissection of the anatomy of the Nobel elite, or at least that not inconsiderable fraction of it which is resident in, and preferably born in, the US. She began by interviewing some 41 of the 56 laureates alive in the US in the early 1960s, and has subsequently extended her survey backwards to the first US laureate, and sideways to holders of what she calls the "41st chair"—scientists whose work is rated as of "Nobel quality" but, for varying reasons, were never awarded the Prize. Through some 200 pages of her book this tiny group are tabulated and cross-tabulated.

We learn that American laureates are more likely than the average researcher to come from an upper-class background (rating below supreme court justices, but above admirals and generals); more likely to be of Jewish and less likely to be of Catholic parentage (for complex reasons); more likely to have gone to elite colleges as undergraduates and especially as Ph.D.

students; and quite likely to have been chosen by, or opted to work with, a present or future laureate early in their career. They have written more papers, more often cited, than the generality of scientists or even other lesser-prestige groups, such as NAS members. They were promoted earlier to Chairs. They are likely to have done their prize-winning work at around 39 (older for the physiology or medicine prize, younger for the physics one) but only get the Prize some 12 years later. Half of the prizes have been won for work carried out in five US institutions.

Once they have received the Prize, their productivity tends to decline, but still remains high compared with other scientists. They accumulate many more honorific awards; they help construct new laureates; as they grow older, many turn towards philosophy.

There are a number of possible reactions to this careful compilation of data; for many professional scientists, it is likely to be an unsurprised "so what?", as they see so many of their rule-of-thumb categorisations confirmed, coupled with an enjoyable guessing game as they try to assign the unattributed quotes with which the Zuckerman text is enlivened. For the empirical sociologist of science, it is pleasing to see such a pretty working out of what Zuckerman's mentor, R. K. Merton, has called "The Matthew effect" in science—to him that hath, more shall be given; a maxim which clearly applies both to impending laureates and the institutions in which they work.

In addition, by showing convincingly that the Nobel award is neither a pure accolade of merit or part of a self-fulfilling prophecy, but is a combination of achieved and ascribed glory, Zuckerman has gone a little way towards demystifying the Prize. Laureates are neither born nor made, but are produced by one of those well known but little understood interactions. She has thrown up some further empirical 'puzzles', such as that of the religious background of laureates, and provided a basis for the comparative study of scientific and other elites (for instance, between science and literature Nobel laureates?).

One cannot help feeling, however, that this type of approach leaves many of the central questions untouched. The Prize glorifies the individual scientist, yet in an era of big science, where production, particularly of physics, has become virtually industrialised, most research has become teamwork. Teams cannot win Prizes—except, it seems, for peace. So, either they are unrewarded or some of their members are singled out—theoreticians rather than experimentalists, generally; professors

## Scientists under Hitler

Politics and the Physics Community in the Third Reich

Alan D. Beyerchen

The treatment of German physicists under the Nazi regime had far-reaching consequences both for the outcome of the Second World War and for the course of science for decades thereafter. The author examines this history in detail, basing his research on archival materials in Germany and the United States and on tape-recorded interviews with leading physicists. £12.60

## The Technological Level of Soviet Industry

Edited by R. Amann, J. M. Cooper, and R. W. Davies

The result of a project funded by the Social Science Research Council, the studies collected in this volume make an extensive and balanced survey of Soviet technological achievement available for the first time. £20.00

**Yale University Press**  
New Haven & London

## Complexes & First Row Transition Elements

D. NICHOLLS

An introductory text for students making their first detailed study of transition element chemistry. It concentrates on the first member of each group, since their properties differ significantly from those of subsequent members. The first part of the book deals with the chemistry of complexes—a topic of central importance to the study of transition elements. Throughout the text emphasis is placed on the properties and reactions of metal aquo-ions and the donor-acceptor properties of transition metal compounds.

£3.95 paperback

## The Heavy Transition Elements

S. A. COTTON AND F. A. HART

A detailed account of all the transition elements except the first row (3d series). The book features a discussion of lanthanides and actinides, with emphasis on recent advances in their structural chemistry.

hardcover £8.95 paperback £4.95

To order a copy of either of these books, please send the correct amount plus 50p per volume carriage, to Technical Book Services, P.O. Box 79, Maidenhead, Berkshire SL6 2EG.

### THREE DIMENSIONAL RECONSTRUCTION IN BIOLOGY

The Late W. A. GAUNT and P. N. GAUNT

First published under the title 'Microreconstruction' by the late Dr. W. A. Gaunt, this book was a unique and highly significant work embodying the experience of a distinguished career. Since then, several new techniques such as cinematography, stereo-photography, holography and stereology have been developed. Therefore the book has been revised and up-dated and added to by the original author's son.

The book remains the only one on the subject of 3-D reconstruction in microscopy. It is very specialised and of the highest level. A comprehensive bibliography is included. Postgraduate researchers and senior workers in the biological sciences, especially Human Anatomy, will regard this book as a necessary addition to their libraries.

## The CUBISM of IDEAS MANIFESTO

Copyright 1973 & 1974 by MORRIS REDMAN SPIVACK, the originator  
Poste restante, Reykjavik, Iceland

It is self-evident that a theory of knowing Nature must have the same structure as Nature itself, but what is the "structure of Nature"? The recognition of this structure was delayed for these many centuries and millennia only by the late development of physics (particularly theoretical physics) and the lack of a parallel or integral dialectics. But at last, in the CUBISM of IDEAS, which I have by great good fortune discovered, we have the basic principle in hand!

### THE ACT OF REASON—

There is a blind spot in the dialectics of Aristotle, Hegel, Marx, Engels and Mao — "every idea implies an opposite idea" is only half the truth, every pair of ideas implies an opposite pair of ideas. Not two units but four *are necessary* to constitute the act of reason. In the constitution of light, we have magnetism (*bipolar*) and electricity (plus and minus) = 4 terms. In my theory of knowledge (also), ideas are quadratic, not dual!

The CUBISM of IDEAS is absolutely fundamental in all the arts and sciences. It also mediates between the physical and metaphysical worlds. It has deep roots in the soul or the religious instinct of man, which cannot be ignored in psychology — as Carl Jung demonstrated, and as depicted in the mystical scriptures and art of the great religious faiths, and even in primitive cosmologies.

It provides us with a faithful mirror of reality and at least a metaphor of ultimate truth. It connects physical, psychological, and spiritual reality thru their common fundamental structure — and therefore provides the foundation for a new psychology of the future, as well as a new art, which will give society its true and pre-destined dialectical unity.

Any perception is already dual, because every percept is viable only with reference to the background out of which it arises and from which it is distinguished. Even so it is only on the level of the nerve-sensor — commanding a reflex but no more, integrative thinking, which is the integration of percepts, is therefore necessarily at least quadratic, and all knowledge, whether conscious, unconscious or subconscious, is quadratic at base.

By raising and also limiting the dialectics to four numbers or dimensions, but maintaining a symmetry of 2/2 so that pairs can cross each other, I universalize the dialectics, and elevate it to equivalence with physical law. This is the double dialectics . . . the first and only basic advance in the dialectics in 3,000 years. The interpenetration of two pairs of ideas in the double dialectics brings the cubism of ideas into existence.

The CUBISM of IDEAS gives knowledge photonic form. If you want to believe that knowledge is light, then you must admit the existence of photons or quanta of reason.

Pairs of ideas fuse or disengage in these photons or quanta of reason. In doing so they gain or release energy. This energy is measured by the power of the ideas to influence our thoughts, not in "ergs". When idea-pairs unite, we imagine there is a spark — new knowledge always appears to us like a flash. This might be compared to the *photon* of light released when an *electron* jumps orbit, or is transformed to light by collision, thought is incandescent . . . it is illumination . . .

The photon of thought appears in memory as the "light of experience" or the "light of the past". Below the surface, it is the substance of dreams and intuitions.

The CUBISM of IDEAS controls the higher mental processes, permeates the subconscious, turns chaos perpetually into order, and forms the very fibre of our intuitions.

If not for dialectical control, we could not stand upright! And not only the mind, but the *entire* body (dancers may note) is a dialectical instrument.

Man is a part of Nature, with its wonderful waterfalls, and oceans, trembling mountains, rolling plains, shooting stars, and spiralling galaxies. But he is an intelligent part — and his thinking continually transforms the world. *Structural fitness* is one of the criteria of truth. *Are we fit for our environment?* Yes, for our natural environment. The degradation of the environment comes from the fact that we have not yet learned how to make our minds work as if Nature *herself* were directing our enterprises. Therefore, we must take the problem of the structure of knowledge seriously.

There will be many men in the future who will be able to use the new dialectics in grand leaps of the imagination and with fantastic effectiveness. It is the greatness of the theory of relativity that the formula holds good for all substitutions of co-ordinates. In the CUBISM of IDEAS, the structure holds good for all substitutions of terms or pairs of terms.

Einstein figured the physical universe as *pure geometry*. If we believe this to be true, we should try to utilize this geometry in our art. There is no other way in which this can be done but by the CUBISM of IDEAS. By this means our art will reflect at least a bit of the ultimate reality.

The CUBISM of IDEAS is as important for *modern art* as was the discovery of the "golden number" (or golden proportion) by the ancient Greeks. It is a philosophy of art face to face with elemental Nature — at the very sources of experience. Such an art shares with Nature her eternal qualities.

Disorder and chaos in our outer and inner worlds arises from errors of thought — the break with the universal. But it is not Nature that is awry, but we. If we put order into our thinking, we shall be able to restore order into our world.

Mankind needs beauty as the Earth needs rain. Beauty itself is a message to mankind (the voice of Nature). The CUBISM of IDEAS is a theory of beauty. For the sources of beauty you have to look deep — seek contact with universal truths. The CUBISM of IDEAS gives art its inner light. It is the implications hidden in the concrete — the real hidden in the abstract — it is the quadrate-essence of philosophy and science, aesthetics and art.

It is the metaphor of metaphors, self-revealed at the very moment when you most need it and least expect it. It tells you secrets of the things you see and hear — gives you a glimpse of the ultimate realities.

It is a unity of unities — its tools are thesis and antithesis in double array.

Pairs of ideas act on each other like flint on flint to produce the spark of enlightenment. It is the most modern means of expression for all the arts — with infinite applications waiting to be made — it is itself an inexhaustible well of inspiration (as I have experienced it). For these reasons The CUBISM of IDEAS is the herald of a new renaissance in all the arts.

The CUBISM of IDEAS, 18pp. script, offset folio, unbound. \$5.00 (U.S.) per copy, by sea mail (air extra). CENTRUM MUNDI for EXPERIMENTAL DIALECTICS and the CUBISM of IDEAS, Morris Redman Spivack, Founder, Poste Restante, Reykjavik, Iceland.  
The above is an EXTRACT from PART I of the MANIFESTO.

## Book Service

**Nature is pleased to announce a new book-ordering service to readers throughout the world.**

To obtain one or more of the titles listed opposite (all recently reviewed in **Nature**) simply complete and return the order form (or a photocopy) or write giving **full** details. Orders must be accompanied by a cheque (personal or otherwise), postal order or money order for the total cost. **Postage (surface mail) and packing is free.**

Payment from overseas may be made in any currency at the prevailing exchange rate. Cheques should be made payable to **Nature.**

**As all titles are ready for immediate despatch, we can guarantee a fast and efficient service.**

All orders should be sent to:

**Nature Book Service  
4 Little Essex Street  
London WC2R 3LF**

## New from Elsevier

### Monitoring Underground Nuclear Explosions

by OLA DAHLMAN and HANS ISRAELSON

A comprehensive ban on all nuclear weapons testing is one of the key issues in today's arms control negotiations. Here, the authors present a complete summary of all the arguments put forward on this issue, reviewing both the technical capabilities and the political requirements of monitoring a test-ban treaty.

1977. x + 440 pages. ISBN 0-444-41604-8. \$49.00

### Geostatistical Ore Reserve Estimation

by MICHEL DAVID

*Developments in Geomathematics, 2*

The first textbook in English on the subject, this book provides the reader with all the information necessary for the application of the geostatistical method of ore reserve estimation in the mining industry.

1977. xx + 364 pages. ISBN 0-444-41532-7. \$39.75

### Marine Manganese Deposits

edited by G.P. GLASBY

*Elsevier Oceanography Series, 15*

A definitive account, by many distinguished authors, of the distribution, geochemistry, mineralogy, internal and external structure, and rate and mechanism of formation of manganese nodules from all types of environment. It is the first time that information on all aspects of manganese nodules has been assembled in one volume and the comprehensive nature of the review suggests it is likely to remain the standard work on this subject for a considerable time.

1977. xvi + 536 pages. ISBN 0-444-41524-6. \$49.00

### Patterns of Evolution

As Illustrated by the Fossil Record

edited by A. HALLAM

*Developments in Palaeontology and Stratigraphy, 5*

This up-to-date review of modern advances in evolutionary palaeontology outlines the significant contribution that modern palaeontology can make to the study of evolution.

1977. xiv + 578 pages. ISBN 0-444-41495-9. \$69.50

### Styles of Folding

*Mechanics and Mechanisms of Folding of Natural Elastic Materials*

by ARVID M. JOHNSON

*Developments in Geotectonics, 11*

Based on the observation that most folds in rock do not resemble sinusoidal waves but, rather, concentric, kink and chevron forms, the author explains the various fold styles one can recognize in the field and in the laboratory.

1977. xx + 408 pages. ISBN 0-404-41496-7. \$49.95

### Mineral Crushing and Grinding Circuits

*Their Simulation, Optimization, Design and Control*

by A.J. LYNCH

*Developments in Mineral Processing, 1*

The size reduction of minerals and rocks is already a large operation in terms of total annual tonnage processed and is increasing in size as the world's requirements for metals, industrial minerals and crushed stone increases. This book reports on the considerable work carried out in recent years on circuit simulation for optimization and design purposes, and covers: mathematical models of crushing, screening, grinding and hydraulic classification processes; their use for circuit simulation, optimization and design; and the requirements, techniques and other aspects of circuit control.

1977. xii + 336 pages. ISBN 0-444-41528-9. \$49.50

### Precambrian of the Northern Hemisphere

by L.J. SALOP

*Developments in Palaeontology and Stratigraphy, 3*

The rapidly developing field of Precambrian geology is producing an abundance of new material which necessitates a constant revision of ideas. In this work, Professor Salop proposes new stratigraphic terminology to meet the requirements of this new data.

1977. x + 382 pages. ISBN 0-444-41510-6. \$59.25

### Remote Sensing in Geomorphology

by H. Th. VERSTAPPEN

This book deals with the application of remote sensing technology to the study of landforms, including both their genetic and environmental aspects. Extensively illustrated, it emphasizes the principles and methodology of image interpretation of geomorphological phenomena such as landforms and landforming processes.

1977. x + 214 pages. ISBN 0-444-41086-4. \$39.95

# ELSEVIER NORTH-HOLLAND<sup>INC</sup>

Circle No. 08 on Reader Enquiry Card.

rather than graduate students, generally; men rather than women, generally; qualified scientists rather than the technicians on whom their work depends, always.

The Prize typifies the myth of 'science' and obscures its reality. It emphasises the hierarchical and authoritarian shape which science in the late twentieth century has come to take. Its social functions inside science and in terms of the relationships between science and society, are both symbolic and substantive, and proper

matters, one would have thought, for a critical sociologist to discuss; yet in all of Zuckerman's pages scarcely a mention is made of such questions. Indeed, it has so far been left largely to scientists themselves to voice such doubts. It would be nice if, now she has done such a thorough piece of internalist empiricism, she would move on to these richer and more complex questions. □

Steven Rose is Professor of Biology at the Open University, Milton Keynes, UK.

## Dazzling firmament

Rainer Goldsmith

*The Pursuit of Nature.* By A. L. Hodgkin, A. F. Huxley, W. Feldberg, W. A. H. Rushton, R. A. Gregory and R. A. McCance. Pp. 180. (Cambridge University: London, New York and Cambridge, 1977.) £7.50.

PRY the poor reviewer, a mere mortal, confronted with a book of essays the authors of which are the living immortals of his discipline. Praise will be interpreted as sycophancy; criticism is tantamount to lèse-majesté. Yet the task must be done, and this fool will step in where wiser angels fear to tread.

The six essays, collectively entitled "Informal Essays on the History of Physiology" are mixed bags containing reminiscences, anecdotes, historical analyses, futuristic speculation, straightforward review, and personal prejudice. They make for varied reading; hardly ever boring, in part thought-provoking and often leaving the reader gasping with admiration at past achievements.

Outstanding among the six is the contribution of Feldberg, "Reminiscences of an Eye-Witness", being an account of the discovery and confirmation of the nature of synaptic and neuromuscular transmission. The lively and very personal style of the essay graphically reflects the enthusiasm and excitement of two or three highly creative years, interspersed by lobster dinners to celebrate successful new findings. One may wonder, however, if Feldberg really contributed only the key of eserine and the eserinated leech muscle to this remarkable period in physiology. Twenty-five years after the event, your reviewer began his scientific career in the very room in which these momentous advances were made: the ceiling was crumbling, the teak benches were uncommunicative witnesses of their past glory—just in one cupboard did the ghosts still linger, the shelves were marked Dale, Feldberg, Brown and McIntosh.

In general, the other essays are also best when the authors write about their own experiences or their immediate interests. The last quarter of Rushton's essay, the piece on colour vision, the *femme fatale* by whom he is so willingly seduced, is entertaining, informative and provocative, indicating that discoveries still await the lucky or the hardworking. The rest, though not up to the same standard, can hardly fail to please. Gregory's vivid account of a single afternoon's work which led to the discovery of secretin and the frustrating tale of the discovery, rejection and rediscovery of gastrin, are clearly very near to his heart.

McCance's contribution is a staccato, somewhat disjointed, review of perinatal physiology interspersed with acid comments on political matters, climaxed by an attack on ethical committees "which shackle the human physiologist to a politically-minded and usually uncooperative public". A

clearer explanation of what the physiologist is about would bring about greater cooperation.

What of the two brightest stars in this dazzling firmament?, the Nobel laureates: your reviewer is now skating on very thin ice. Sir Alan Hodgkin gives a dry, low-key, understated account of his own and other experiments which led to the explanation of the nature of the action potential. His picture of Cambridge in the 1930s is that of another world. But, with decreasing funds, we too may have "to think hard to decide what is right" and then "start in a bare room and build most of our equipment". The writing lacks Feldberg's sense of immediacy and involvement; it seems that life was an orderly procession from Cambridge to New York and the grand tour of the United States with just time for a less-than-one-dollar-a-day holiday in Mexico and then back to Cambridge and Plymouth. Great events are curiously muted: the tribulations of war are recalled by the fact that he did not bother to keep his copies of the *Journal of Physiology*, their alleviation by marriage to Peyton Rous' daughter, and his ability to think about nerves again; the 1947 fuel crisis during which all Cambridge and indeed the rest of the country froze, is marked only by the chance to do experiments at  $-4^{\circ}\text{C}$ . It is an account of a dedicated scientist hard at work undisturbed by counter-attractions—how unlike the more frivolous attitudes of a younger generation of Cambridge laureates (see J. D. Watson, *Double Helix*, Weidenfeld and Nicolson).

"Looking Back on Muscle" by A. F. Huxley is a masterly account of the changing views down the microscope over the past hundred years, which lead eventually to the sliding filament theory of the contraction of muscle. It is a stern warning that what is true today may be forgotten tomorrow and that yesterday's discoveries may be nearer the truth than today's dogma.

All in all, a stimulating book requiring a good physiological background to obtain full value. It is a pity that these eminent men allude to so much endowing us with their own immense understanding but in fact leaving most stranded on the shores of ignorance. It is as if the secrets must remain hidden from all save those who have been fully initiated into the circle. It is an enjoyable book for the student, opening the door into living history and introducing him to all the greats, not only these six but also their colleagues and their teachers who constitute the very backbone of physiology. □

Rainer Goldsmith is Professor of Physiology at Chelsea College, University of London, UK.

## Immunity in Evolution

John J. Marchalonis

The first book of its type, taking a comparative study of immunity as the theme to reveal the extraordinary evolution of cellular and molecular mechanisms. It provides a general background on vertebrate evolution and on immunochemistry.

Cloth £10

## The Mammalian Alimentary System

A Functional Approach

David S. Madge

'... of great interest and use to teachers, scientists and advisers working within the field of nutrition or to other persons who must keep pace with the rapid progress within the field of physiology and biochemistry of digestion and absorption.'

*Livestock Production Science*  
'Those who wish to become better informed on one of the essential functions of mammals will find reading this book a rewarding exercise.'

*The Veterinary Record*

Cloth £8 Paper £4.50

## Biological Machines

A Cybernetic Approach to Life

Peter Calow

In recent years biology has moved from a preoccupation with molecular aspects of organisms to the organisms themselves. One way of bridging the gap is through model building. This book gives a definition of systems theory and cybernetics in the context of organismic biology. Questions such as 'What is it about organisms which makes them organisms?' 'How can models help?' are discussed in such a way as to demonstrate to the undergraduate or research worker how model building, systems theory and cybernetics can help biologists towards a rational understanding of living organisms.

Cloth £7.95 Paper £3.95

## Neurological traditions upheld

J. Z. Young

*Mechanics of the Mind*. By Colin Blakemore. Pp. 208. (Cambridge University: Cambridge, London and New York, 1977.) Hardback £10.50; paperback £3.95.

THE brain was the subject of the second series of Reith Lectures in November 1950. At that time I estimated that there might be perhaps 100 competent students of the brain in the world, as compared with at least 100,000 chemists. Since then, many of these latter have joined in the study of the brain; and Colin Blakemore, giving the lectures 27 years later, has to summarise the work of a very larger number of neuroscientists. He has performed the task magnificently and with the help of the Cambridge University Press produced a book of outstanding beauty as well as intellectual interest. There can be few works that contain so much that can stimulate the specialist as well as the layman. Perhaps it is one of the achievements of the Reith Lectures to effect this union. Producing them, one discovers that explaining things clearly is itself a road to discovery.

Blakemore shows this brilliantly in his treatment of the visual cortex, the part of the brain with which he is most familiar. He solves the problem of how to describe the complicated series of visual areas by calling them 'an amazing array of charts, ... a veritable atlas of the world of vision. Each map has a different scale and like the various pages in a real atlas ... the visual maps each emphasise a different component ... colour in one, shape in another ...'. And then, after talking of the 'torrent of information pouring through this labyrinth of maps' he brilliantly describes the effect of a local injury as 'causing a partial loss of the description of the world, a kind of scotoma of knowledge'.

Blakemore is indeed not afraid to use imagery and he does it in a way that calls attention to the important problems—philosophical as well as neurological. 'We seem driven to say that such neurones have knowledge. They have intelligence, for they are able to estimate the probability of outside events'. It is interesting that he hardly ever feels the need to use inverted commas.

Anyone who wants to find out about the nervous system should read this

book. I will bet that even the most sophisticated neuroscientist or clinical neurologist will find something he did not know before. Apart from everything else he will find a great deal of history, some of it most ingeniously illustrated, sometimes in excellent colour. Personally, I could do without the photographs of distinguished neuroscientists; most of those that are of people I have known fail to capture their more characteristic expressions.

Of course, the treatment can be criticised here and there. Surely the surprising thing about knowledge of the pineal today is not that its function is 'still uncertain', but that we have learnt so much about it recently. Which reminds me that one of the things one misses is treatment of the neurochemistry of the brain. The index has no entry for amines (but four for animal spirits).

Any discussion of cerebral functions must include the controversial questions of nature and nurture, and the tabula rasa. Blakemore deals with them openly and in the main accurately. There is indeed much evidence that children are pre-programmed for language, but we anatomists are sceptical of the assertion that Weinicke's speech area is larger on the left side even in babies. How do you measure it? Blakemore gives more attention than I would to the hypothesis of specific memory molecules but comes down firmly against it, in favour of a 'transformation of the connectivity of the brain'. He refers to the 'built-in reflexes as the inherent knowledge of Plato', but curiously does not link discussion of this with his own discovery of changes of built-in capa-

Taken from *Utriusque Cosmi* (1619-1621)

cities that are brought on by experience. He rejects "the fantastic notion that every memory is innately within us", but his own evidence is consistent with the conception behind my mnemon hypothesis (which he quotes) that memory is a selective process, involving loss of some channels and improvement of others. Like all good neuroscientists he accepts that neural coding involves putting each item of information into a separate channel, but we all find it difficult to work out the im-

plications of this multichannel method of operating even for simple acts of perception.

To be able to discuss such questions in a review of the book of a series of broadcast lectures that are widely listened to is the highest tribute one can give to the author and to the BBC. Can any other country equal the record of this series? ☐

## Just not cricket

Stuart Sutherland

*Against Behaviourism: A Critique of Behavioural Science.* By Edmund Ions. Pp. xiii+165. (Blackwell: Oxford, 1977.) Hardback £6; paperback £2.75.

THE sport of debunking famous names rarely fails to entertain, and when applied to men as pompous and pre-tenacious as most social scientists it has enhanced spectator appeal. As a demon bowler Edmund Ions is in a class of his own: he dismisses in successive balls Herbert Simon, Morton Kaplan, Karl Deutsch, B. F. Skinner, Rashevsky, Stouffer, Adorno, von Neumann, Kaldor, Hicks, Garfinkel, Goffman, Levi-Strauss and Chomsky. His opponents are a curiously assorted team: were it not for the inclusion of Garfinkel and Goffman one might suppose that Ions was combating the attempt to apply objective methods in the social sciences, but ethnomethodologists can scarcely be accused of that and are declared out for giving "a partial and selective account of human behaviour".

*Against Behaviourism* is primarily an attack on the use of mathematical and logical theories, and of scientific methods of data collection and analysis in the social sciences. Ions argues his case by examining a series of instances where the attempt to be scientific has resulted in banal or useless theories, or where objective methods of data collection have been poorly applied and grossly misinterpreted.

There is plenty of bad work in the social sciences and many of Ions' examples are convincing. Grandiose models of the sort constructed by Rashevsky are empty; cost-benefit analysis invariably involves making arbitrary assumptions; the celebrated discovery of the "Authoritarian Personality" rests on the construction of a loaded questionnaire and the use of a monstrously biased sample; Games Theory is an idealised model of conflict

behaviour; and cliometricians, jurimetricians, psephologists and content analysts often either discover the obvious or make wild errors as a result of unduly restricting both the data they use and their methods of analysis.

Moreover, Ions is surely right in thinking that the very obscurity of many scientific approaches to the social sciences has disguised the fact that much of the work is empty. Model builders often conceal the banality of their thought by the tortuousness of their language. It requires both perspicacity and courage to dismiss as trivial such statements as: "*Hypothesis Two*. Multiple role functions operate on personality systems in such a fashion that the personality systems perceive the objective and values of the decision making units linked by the multiple role functions as more similar than they would if they entered only into single role function." (Morton Kaplan.)

We may agree with Ions, then, that the application of scientific or objective methods is no guarantee of producing interesting findings or arriving at correct conclusions, but he seems to go beyond this and to damn all attempts at objectivity. Yet, the use of intuition can be just as fallible as is demonstrated by the results of studies on the unreliability of unstructured interviews for job selection. One only has to read Arthur Maslow to become aware that the experiential or humanist approach to society may itself result in pretentious banality and silliness. And even if rigorous models are as incomplete as non-rigorous ones, they may still throw light on human behaviour by focusing attention on the ways in which people depart from them.

Ions stigmatises Levi-Strauss for "classifying", though how it is possible to communicate at all without classifying he does not explain. His critique of Chomsky is hard to follow. He seems to think that the attempt to formalise our intuitions about syntax is in itself a bad thing and then goes on to criticise Chomsky for failing to deal with those aspects of language that are completely outside the scope of his theories.

A further problem is that in arguing from example, Ions is himself guilty of one of the main crimes of which he seeks to convict his opponents, namely, dogmatic generalisation based on insufficient evidence. He maintains a consistently fast pace but his bowling is loose and often aimed at the man

not the wicket: any decent umpire would have sent him off the field, but that would have deprived the crowd of considerable amusement. □

## Animal communication in ethological research

John Krebs

*The Behaviour of Communicating: An Ethological Approach.* By W. John Smith. Pp. 545. (Harvard University: Cambridge, Massachusetts and London, 1977.) £13.65.

MORE than any other subject, animal communication has occupied a prominent place in ethological research throughout the past forty years. Lorenz's demonstration that displays of ducks and geese can be used as species-specific taxonomic characters to trace phylogenies; Tinbergen's classic analyses of the motivational basis of displays in gulls; Thorpe and Marler's work on the ontogeny of bird song; and von Frisch's dancing bees are all justifiably recognised as pillars of ethology. In the past few years, although some of the emphasis has slightly changed, animal communication has still played a central role in ethological thinking, exemplified by G. A. Parker and J. Maynard Smith's application of game theory to ritualised displays.

It is perhaps not surprising, in view of the voluminous and diverse literature, that no single person has, since Tinbergen with his *Social Behaviour in Animals* (Methuen, 1953), attempted the daunting task of reviewing the whole subject of communication. There have been notable collections of essays (Huxley's "ritualisation" symposium, Hinde's *Non-Verbal Communication* and Sebeok's *Animal Communication*), but W. John Smith is the first for nearly 25 years to write a comprehensive treatise. Comprehensive is the word: with over forty pages of references, Smith has done an admirable and scholarly job of bringing together the literature up to and including 1976.

Smith's own well known contribu-

tion to the field of communication has been to emphasise the distinction between the *message* contained in a signal (what it might potentially reveal about the communicator) and its *meaning* to the recipient(s). The meaning, measured by the response of the recipient, usually depends on the context. For example, a hypothetical call given by a bird whenever it moves may mean "I am about to attack" in one context, and "I am about to feed" in another. The book leans heavily on Smith's message-meaning distinction: after an introduction in which he clearly defines communication and states the problems he is going to tackle, there are six chapters (including a lot of descriptive examples) dealing with the structure and message content of signals.

The subsequent chapters deal in turn with the motivational basis of displays (a review of the traditional ethological work), the importance of context and the meaning of signals, ritualisation, ecological and other constraints on signalling systems, and finally a critique and reassessment of the display concept. In this final section, Smith points out that the usual preoccupation of ethologists with simple stereotyped displays (releasers) has led to an under-emphasis on the possibility of complex grammatical rules for combining simple components into complex signals. Throughout the book, Smith provides numerous examples, many of them unpublished, which make interesting reading and act as an excellent diluent for the slightly heavy style of the more theoretical discussions.

In such a wide-ranging and thought-provoking book, it is hard to know where to begin in singling out points for discussion, but I will mention briefly a general feature of communication which I believe that Smith may have underplayed. Smith views communication as a cooperative venture between communicator and recipient; displays are acts "specialised to make information available to the recipient" (p69, p195) about the communicator's likely future behaviour, status, location, and so on. This standpoint is emphasised by Smith's statement that manipulation or intentional misleading is a "disturbing possibility" but not one that ethologists have yet discovered. (He inexplicably separates intra- and interspecific deceit—the

latter is well known in, for example, Batesian mimicry.)

I would suggest that far from being a marginally possible aberrance, manipulation, or something very like it, is a central feature of much of animal communication. As Smith emphasises, signals can only evolve if there is an advantage to the recipient in responding, as well as an advantage to the communicator. But this is not to say that the benefits to the two are equal; and it seems inevitable that both participants in any interaction—be it between a territorial stickleback displaying to an intruder or a fledgling blackbird begging from its parent—will strive to get the maximum benefit. Viewed in this light, communicators are always trying to manipulate or persuade recipients, while recipients are increasing their sales-resistance. It is then not at all surprising that displays often provide incomplete information about the motivational state of the communicator (p201): it always pays to be poker-faced when selling a used car.

It also follows from my argument that many display interactions are concerned with assessment ("Is he really as confident as his threat indicates?"). The elaborate courtship rituals of many animals may have as much to do with assessment of the potential mate's fidelity and fecundity as with "helping male and female to cooperate in beginning copulation" (p300). This was brought home to me by the striking result of Erickson and Zenone (*Science*, **192**, 1353–54; 1976). They showed that a male ring dove actually rejects a female who is too willing in courtship. This is a canny reaction: "precocious" females are forward because they have just been stimulated by mating with another male, and it supports the view that ring dove courtship involves assessment by the male of whether the female has already been fertilised. With the traditional ethological view of male courtship as a means of arousing the female to copulate, who would have foreseen that male ring doves would reject avian nymphomaniacs?

While I certainly would not claim that all intraspecific communication involves manipulation and assessment, it just might be useful to bear these ideas in mind when analysing courtship and threat signals. Finally, let me emphasise that Smith's omission of the sort of discussion I have briefly outlined does not materially detract from his enormous achievement in synthesising and appraising such an important subject. □

## PUBLISHING USA INC

### Clinical, Biochemical & Hematological Reference Values in Normal Experimental Animals

Brij M Mitruka MD *University of Pennsylvania*, and Howard M Rawnsley MD *Dartmouth Medical School, New Hampshire*

This book makes available to medical researchers and biologists all the significant information concerning clinical biochemical and hematological reference values of experimental animals. As a source of clinical laboratory values and interpretations of the data, it will be of particular use in evaluation of pathological conditions during experimental studies. The authors emphasize the importance of establishing baseline chemical values in experimental subjects, and by using the quality controlled baseline values provided here the medical investigator should be able to make sound interpretations of laboratory data on his own experimental animals.

288 pages, 148 illustrations  
0 98351 001 X 1977 £17.00

### Drug Therapy Reviews, Volume 1

Russell R Miller Pharm D PhD *New England Medical Center Hospital, Massachusetts* and David J Greenblatt MD *Massachusetts General Hospital, Boston, Massachusetts*, editors

Hundreds of potent drugs are in widespread use and one or two dozen new chemical compounds are introduced into clinical therapy each year: today's physician is greatly in need of accurate, current and clinically oriented information about the properties and actions of commonly used drugs. **Drug Therapy Reviews** aims to fulfill this need. In addition to considering the rationale of drug therapy and the choice among drugs in pertinent clinical situations, the articles in this first volume also come to grips with the details of such therapy. General practitioners, internists, psychiatrists, surgeons, cardiologists, gastroenterologists, chest specialists, neurosurgeons and specialists involved in patient care will all find this book of immense practical value.

272 pages, 20 illustrations.  
0 89352 001 2 1977 £19.50 Volume 2 in preparation

### Interpretation of Biochemical Multitest Profiles: An Analysis of 100 Important Conditions

Paul L Wolf MD *University of California*

The author presents biochemical profiles on a diverse and important group of conditions in 100 typical patients. Histories and physicals of each patient are presented, the biochemical multitest panel is included, and the significance of the increased/decreased values for the patient are defined. Important literature is cited relevant to the abnormality in the biochemical test in the specific disease.

312 pages, illustrated  
0 89351 002 0 1977 £14.65

### Quality Control in Laboratory Medicine

John B Henry MD *State University of New York*, and Joseph L Giegel PhD *DADE Corporation, Florida*

A group of American and international experts, primarily in clinical chemistry and clinical pathology, review the state of the art in quality control and make recommendations for further improvements, including standardization in methodology and utilization of the clinical laboratory. Special emphasis is placed on enzyme diagnosis and testing procedures, measuring the activity of aspartate aminotransferase, and profiling in intravascular coagulation. The authors establish sound criteria for the creation of profiles in health and diseases.

350 pages, 127 illustrations  
0 89352 008 X 1977 £20.00 approx

### Cholesterol Metabolism & Lipolytic Enzymes

J Polonovski *University of Paris Saint-Antoine*

28 contributions from France, Great Britain, Israel, the Netherlands, Sweden and the United States explore the latest research advances concerning cholesterol biosynthesis, bile acid formation, cholesterol transport, esterification, certain aspects of hypercholesterolaemia, the interaction of lipolytic enzymes with protein cofactors, and the interfacial conditions of lipolytic enzyme activity. Pathological aspects are also discussed.

211 pages illustrated  
0 89352 010 1 1977 £19.50

### NEW BOOKS FOR 1978

#### Practical Guide to Medicine and Veterinarian Mycology

Professor R Vanbreuseghem, *Free University of Brussels & Institute for Tropical Medicine, Antwerp*

This is a comprehensive examination of the diseases caused by fungi and yeasts and the parasites that carry them. The book is divided into three parts: Mycoses and Pseudomycoses; The Agents of Mycoses and Pseudomycoses; Techniques and Culture Media.  
January 1978

#### Atlas of Soil Science

Duchaufour  
translated by DeKimpe

Soil constitutes a complex environment, generally in equilibrium with all the ecological factors — climate, vegetation and mineral parent material — whose actions it integrates. The author offers an ecological system of classification based on 'evolution sequences': soils are assigned a place in relation to others from which it differs either by an intensification of the basic ecological process, or by superimposition of another process on the basic process. The ecological genesis of the soil profile, from which originate its transitional features and consequently the problems it causes the pedologist, can thus be understood.

December 1977/January 1978

# New neurochemical tracers

**[phenyl-4(n)-<sup>3</sup>H]Spiperone** TRK.570  
(Spiroperidol)  
20-30Ci/mmol

For dopamine receptor studies. Much more potent than haloperidol in most studies.

**[G-<sup>3</sup>H]Kainic acid** TRK.566  
2-10Ci/mmol

For glutamate receptor studies. An agonist to, and 1000 times more potent than, glutamic acid.

**[N-methyl-<sup>3</sup>H]Diazepam** TRK.572  
30-60Ci/mmol

**[2-<sup>14</sup>C]Diazepam** CFA.591  
40-60mCi/mmol

One of the most widely used drugs in medicine. High affinity receptors have recently been discovered in brain tissue.

**D-Ala<sup>2</sup>-[tyrosyl-3,5-<sup>3</sup>H]enkephalin-**  
(5-L-methioninamide) TRK.564  
15-30Ci/mmol

A synthetic enkephalin analogue for opiate receptor studies. It binds as tightly as met-enkephalin but is less easily degraded.

**Also available.**  
**D-Ala<sup>2</sup>-[tyrosyl-3,5-<sup>3</sup>H]enkephalin-**  
(5-L-leucine amide) TRK.568

# Expression of the genetic apparatus

John Scaife

*Gene Expression*. Vol. 3: Plasmids and Phages. By Benjamin Lewin. Pp.942/928. (Wiley: London and New York, 1977.) Hardback £24; \$40.65; paperback £10.25; \$19.50.

READERS of this journal will be familiar with the changing fortunes of microbial genetics in recent years. In the early to mid-1960s, its practitioners saw the genetic code unveiled and the birth of the operon. Five subsequent years of plenty were followed by a decline, as interest turned from lower to higher organisms and their development. Now the wheel has come full circle as the potential of bacteria and their viruses in genetic engineering is understood. As if to mark this development, the new volume in Benjamin Lewin's series on *Gene Expression* is devoted to plasmids and phages. These genetic elements have made a massive contribution to our understanding of the mechanism of heredity at the molecular level. They also happen to be suitable vectors of recombinant DNA made *in vitro*.

This series of books is intended to provide a critical analysis of the organisation and expression of the genetic apparatus at the molecular level. In this context, the present volume gives an excellent entry to the literature for advanced students of molecular genetics. It will also be a valuable reference work for final-year undergraduates. Rather than write a textbook, the author has manfully undertaken to review the whole field in some detail. The enterprise has been a profitable one. Indeed, his account of some systems is more incisive and digestible than the available specialist reviews. Readers will particularly appreciate the presentation of experimental protocols and models in diagram form, although grey rather than a brighter second colour can lead to ambiguity in some figures. Taken as a whole, the book with only a few important inaccuracies brings the general reader painlessly up to date in a fast-moving field.

Plasmids are now known to occur naturally in bacteria as widely different as *Staphylococcus* and *Agrobacterium*. The first of its kind to be discovered was the fertility factor F, which promotes mating between strains of *Escherichia coli* and, as it turns out,

other related enteric bacteria. It is a circular DNA molecule which, although much smaller (~2%) than the bacterial chromosome, is big enough to carry nearly 100 genes (94.5 kilobases). It can exist as an autonomous element but may insert into the chromosome.

Plasmids can vary in a number of respects. Some are unable to insert in the chromosome, others cannot mediate their own transfer by mating. They can carry genes of considerable importance in agriculture and medicine. For example, R factors are plasmids which confer multiple drug resistance on the host bacterium. Pathogens containing R factors have become a serious clinical problem, particularly since they can often transfer multiple drug resistance to other bacteria. Other plasmids determine the ability of some soil bacteria to utilise unusual materials such as camphor and toluene. At the same time, plasmids interest the molecular biologist as excellent tools to study, for instance, DNA replication *in vivo*, since they may be regarded and, more importantly, manipulated as dispensable analogues of the chromosome itself.

The bacteriophages form two large groups. The virulent phages are obliged to multiply on infecting their host. Most of them kill the host in the process. The important virulent phages of *E. coli* are discussed in this book, including the double-stranded DNA phages T4, T3 and T7, the single-stranded DNA phages  $\lambda$ X174, S13, f1 and M13, and the RNA phages f2 and Q $\beta$ . The temperate phages do not always kill the host. On infection they may enter the prophage state to give a lysogenic bacterium, in which the phage DNA is preserved as part of the host's hereditary material. There are temperate phages which are directly important to man, such as the corynebacteriophage  $\beta$ , which determines the toxin of diphtheria. Certainly the most studied of this group is phage  $\lambda$ , which is discussed in great detail in this work. Some readers will regret the omission of the phages of *Bacillus subtilis* and *Salmonella typhimurium* from this book. I was surprised to find the coliphage P1 given short shrift. P1 has the distinction of existing in the autonomous state as a prophage, qualifying for inclusion as both plasmid and phage. It is also an important vector of host DNA in genetic analysis by transduction, without which fine structure genetic mapping would be impossible.

The book devotes separate chapters to the different genetic elements, a profitable treatment for readers at the research level. A fuller index would probably have made it more acceptable to the general reader. The two opening

chapters describe the transfer material between bacteria, as naked DNA in transformation, and by mating (conjugation) between bacteria. These chapters provide a good account of the techniques of genetic mapping, and of the principles and mechanisms involved. They provide the background for later plasmid and phage chapters, and include discussion of the F factor. A separate chapter on plasmids focuses on R factors and col factors (which determine macromolecular antibiotics called colicins).

The molecular genetics of plasmids is examined in some detail. The mechanisms controlling plasmid copy number, transfer functions of F and related R factors, the molecular structure of plasmids as deduced from heteroduplex mapping techniques and the incompatibility between related plasmids in the same host are discussed in these early chapters. They also provide an informative account of studies on insertion sequences. These are specific DNA sequences, approximately 1,000 base pairs long, and are found in plasmids and at various sites on the *E. coli* chromosome. Interaction between insertion sequences can mediate insertion of F into the chromosome. Of perhaps even greater importance is the discovery that some R factor genes for drug resistance lie between insertion sequences and are transposed by them to new phages, plasmids and chromosomal sites. These movable genetic packages, now called transposons, provide a means by which drug resistance and other properties may reassort in nature.

The phage  $\lambda$  opts for lysogeny or growth shortly after infection. The molecular nature of this decision is not completely understood but it clearly depends on competition between mutually exclusive patterns of transcription. Of major importance in this competition are the factors facilitating or denying to the host RNA polymerase access to phage promoters. The disentanglement of these regulatory circuits by mutants, sequencing and other approaches makes a fascinating story. Dr Lewin's account of its development is one of the best currently in print. The virulent phages, T7 and T3, which are similar in size to  $\lambda$ , probably have simpler circuits. They code for an RNA polymerase of their own, and their growth is regulated at the level of transcription. The RNA phages, on the other hand, have important controls operating at the level of translation. The genetic organisation of RNA phages has rarely been elucidated by direct sequencing, since these phages do not recombine.

The integration of  $\lambda$  prophage into the host chromosome provides a

beautiful example of site-specific recombination, which may serve as a model for the movement of transposons and analogous elements in higher organisms. The interaction uses enzymes which recognise different, specific, base sequences (recently elucidated by Landy and Ross, *Science*, **197**, 1147; 1977) in the phage and host chromosomes, and promote crossovers between them. Most recombination, of course, is not limited to short sequences. Generalised recombination occurs between parental molecules of all phages but those with RNA as their genetic material. Models for the different types of recombination are discussed by the author in several chapters; and he gives a fair account of the current ideas in a changing field.

Most of the information encoded in a phage genome relates to the synthesis of the phage coat. More than 50 genes of phage T4 have this function. Notably, in phages T4 and  $\lambda$ , the assembly pathways have been mapped out by recording the stages reached in different maturation mutants. These

systems provide a way of studying spontaneous self-assembly and structural interactions between repeating subunits. They also lead to the conclusion that *in vivo* assembly is not spontaneous but is assisted by special accessory proteins. This is an area where Lewin's extensive diagrams and plates are most helpful.

*Plasmids and Phages* encompasses a wide range of modern techniques and ideas. They are described simply and well; and this presentation shows the dense logical and experimental substructure from which molecular genetics has grown. In addition, the author provides an excellent account of the early development of the major themes which continue to engage interest in the field. It is therefore fair to say that this book is valuable, not only as a research text but as a source which should be of considerable value to the future historian of molecular biology.

John Scaife is Reader in Molecular Biology at the University of Edinburgh, UK.

## Genetic engineering journalese

R. J. C. Harris

*Biohazard*. By Michael Rogers. Pp. 209. (Knopf: New York, 1977.) \$8.95.

THE title of the book does not alas describe it. What purported to be a description, in journalist's language, of the biohazard problems was a totally different book. The blurb of the cover outlines both the contents and the style: "Immediate, fascinating, frightening in its implications, *Biohazard* is the story of a current and major scientific controversy". The writer, Michael Rogers, portrays a "moral and scientific confrontation" reported "as it happened and where it happened".

Rogers outlines, and devotes most space to, the "history-in-the-making" meeting at Asilomar in early 1975 (pp51-100). He began, too, without an understanding of recombinant DNA; for him, then, the calculated breeding of plants and animals by selection and mutation was, in essence, genetic engineering. In chapters 2 and 3, we are led through the history of DNA (starting with Miescher and ending with Avery *et al.*) and acquainted with *Escherichia coli* and phages. The three chapters on Asilomar are preceded by

a recounting of the moratorium. Paul Berg enters the story with his dilemma about SV40 but fails to get the brief description accorded to most of the actors. Herbert Boyer, a soft-spoken San Francisco biochemist, discovered *EcoRI* which produced the "sticky ends" that allowed not only the original DNA strands to rejoin, but the coupling of the cut-ends of foreign DNA.

It is not clear how excerpts from the Asilomar meeting were reproduced with the apparently original comment of selected delegates. The taped official record was (p54) to be held for 50 years (*sic*). Did Rogers have his own tape, did he evade the 50 year rule, or had he merely adequate shorthand? In any event, this poses a general problem. Most scientists, even the most glib, prefer, if they are to be quoted verbatim, to see what they are purported to have said before it is published. Is it not courteous to ask the prior consent of the scientist before attributing to him remarks of any kind? These steps may have been taken for the US contingent where their scientists were usually quoted—for example, David Baltimore ("trimly bearded and clad in an embroidered Levi shirt") and Ray Curtiss ("imposing, long-haired") but not, probably fortunately, for most of the British. One who may recognise himself talks about K12 ("nice, quiet, boring person at least as far as his colon is concerned"). Two Britons at Asilomar are quoted (or misquoted) by name—E. S. Anderson from Colindale ("portly, imposing gentleman") and

Sydney Brenner ("bushy eyebrows, gleaming eyes, non-stop animation, mid-way between leprechaun and gnome"). One group, at least, was missing: those whose experience was in the realms of infectious diseases. Anderson drew careful attention to this (p63) and "glared coldly" as he did so.

Summing-up the meeting (at which some 10% were journalists, anyway) is well described. The problem is so acute—more akin to asking a committee to write a poem—that the most recent US meetings on recombinant DNA have compromised the organisers by drafting a statement (a letter in this case) and seeking adherents from among the meeting. Although Asilomar was attended by many microbiologists from different countries, only the British were singled out and the Russians are mentioned once.

The single chapter devoted to a discussion of biohazards begins with: "the only recorded civilian biohazard fatalities—the deaths of individuals who were in no way connected to a laboratory—occurred in London, in March 1973" and refers, of course, to the smallpox incident. Rogers uses this accident (albeit from a well-known human pathogen) to justify the widely felt concern about "new infectious organisms containing novel genetic material". Prominent among the concerned was, of course, Mayor A. E. Velluci of Cambridge, Massachusetts. The possibility (Velluci's "disease that can't be cured—even a monster") of a public, or ecological, disaster added bright new ammunition for the "town" in its confrontation with "gown". The author describes in some detail Building 41 at the National Institutes of Health at Maryland, which was built apparently for \$3.5 million, to handle the viruses which were expected by the US to emerge from the accelerated Cancer Program. The methods of handling biohazards, in genetic engineering research, might well have been stressed at greater length. In the UK, the Biological Safety Officers and their Safety Committees exist solely to assure the public (in the final shape of the Health and Safety Executive) that the containment level selected, whether this be physical or physical/biological, matches the risk and is thus safe.

The next chapter diverges from the story of succeeding conferences at which Rogers is becoming more confident, and more of a *confident*; he reverts to restriction enzymes, gel electrophoresis, complementary DNA sequences, molecular cloning and shotgunning. A crucial issue which is mentioned as a possibility is that of "libraries of cloned gene sequences" whether these be of prokaryotic (E.

## Posture

**Robert Roaf**

December 1977, viii + 100pp., £3.80/\$7.50 0.12.589350.7

Reference is frequently made to 'good' or 'bad' posture, but the criteria are seldom defined. The term 'posture' itself is difficult to define, because without a qualifying adjective it has only half a meaning. It has been defined as the relative disposition of the limbs and body, and as an expression of the body's equilibrium and balance. Professor Roaf considers the criteria for good posture to be balanced movement and minimum muscular exertion in adapting to the needs of the moment. He draws attention to the many diverse areas in which posture is significant — in cultural and sporting activities, and in communication between individuals and groups — and he discusses the origin and development of the upright position in humans, the physiological mechanism of postural control, and the causes of poor posture and its remedies.

## Group Theory and Computation

edited by **Michael P. J. Curran**

December 1977, xiv + 118pp., £5.80/\$11.35 0.12.200150.8

This volume is based on the invited papers given at a Summer School on Group Theory and Computation held under the auspices of the National Committee for Mathematics of the Royal Irish Academy. Together, they present in a concise form both the state of the art in certain areas of finite group theory and also a review of permutation groups.

### Contents

*Marshall Hall Jr.*: Computers in Group Theory. *John Leech*: Computer Proof of Relations in Groups. *J. H. Conway*: The Miracle Octad Generator. *J. H. Conway*: A Quaternionic Construction for the Rudvalis Group. *Peter M. Neumann*: Finite Permutation Groups, Edge-Coloured Graphs and Matrices.

## APIC Studies in Data Processing No. 13

## Software Engineering

**R. H. Perrot**

December 1977, xii + 204pp., £8.20/\$16.00 0.12.551450.6

This book records the papers presented at the British Computer Society's Symposium on Software Engineering held at the Queen's University of Belfast in April 1976. It defines the working tools of the software engineer, reviews the range of methods presently available to him and suggests further improvements. The publication is devoted to practical measures to alleviate problems in the use of currently available software engineering tools and it has an optimistic and forward looking approach. For the present, the primary consideration is how to live with existing software products and to use them more effectively. Several well engineered systems are examined and a study made of the lessons to be learnt from them.

## European Monographs in Social Psychology 12

Series editor: **H. Tajfel**

## Decoding Oral Language

**Astri Heen Wold**

January/February 1977, approx. 250pp., £8.50/\$16.50 0.12.336250.4

This book is the result of a long programme of theoretical enquiries and experiments on aspects of time in language and communication. Its emphasis on the temporal dimension in psycho-linguistic analysis makes a sharp contrast with current trends in Chomskian and post-Chomskian semantic theory, which have tended to *spatialize* and *deterioralize* language. A linguistic theory which treats as irrelevant conditions such as memory limitations, distractions, errors and shifts of interest, argues the author, cannot hope to come to terms with the realities of language as a series of intentioned acts of communication between one speaker and another. This study accordingly attempts to combine a soundly-based *social-psychological* perspective on language with an analysis of *individual processing*.

## Studies in Convection

Theory, Measurement and Applications

Volume 2

edited by **B. E. Launder**

November 1977, viii + 224pp., £8.80/\$17.25 0.12.428002.6

This series aims to present major contributions to the understanding of convective transport phenomena; particularly in turbulent flows. This, the second volume in the series, is devoted entirely to various aspects of convection relating to chemical reaction; in recognition of the growth and expanding interest in combustion research generated by worldwide concern about pollution and the energy crisis. Combustion, as an area of research, has benefited from progress made in the study of non-reacting flows, which has engendered new methods of analysis, new instrumentation and a general understanding of turbulence.

## Measles Virus and Its Biology

K. S. Fraser and S. J. Martin

December 1977, approx. 250pp., £9.80/\$19.25 0.12.265350.5

This first book in the new series, *Experimental Virology*, is at the forefront of research on the measles virus, yet its contents are still within the grasp of the students of medicine, microbiology and biochemistry. The work sets out the problems of measles and its complications and relates them to recent knowledge of the biological character of the virus. The authors have placed particular emphasis on the predilection of the virus for lymphoid tissue and its ability to set up persistent infection through defective modes of replication. They have stressed too the need to find out more about the relationship between measles virus and immune responses. The significance of such interactions can be seen clearly in the pathogenesis of conditions such as measles enteropathy, subcutaneous sclerosing panencephalitis, multiple sclerosis and certain auto-immune diseases.

## Microbial Ecology of the Gut

edited by R. T. J. Clarke and T. Bauchop

December 1977, xviii + 410pp., £13.50/\$26.50 0.12.175550.9

This book sets out, by contrast, to provide a full and integrated account of the microbial ecology of many different animals. The multi-disciplinary origin of the contributions suggested the adoption of a broad rubric rather than separate specific studies: information has been organized within a framework of general questions — what kinds and numbers of organisms are present? What are their activities, and to what extent are these activities performed? Thus the book includes discussions on the bio-chemical activities of microbes in the gut, and fermentations in the hindgut and foregut. Other chapters deal with types of microbes; techniques of study; a gnotobiotic approach to ecological studies; protozoa in the rumen; and a mathematical approach to the turnover of fermentation end-products.

## The Analysis of Organic Materials An International Series of Monographs

Series editors: R. Belcher and D. M. W. Anderson

## Instrumental Organic Elemental Analysis

edited by R. Belcher

December 1977, xii + 300pp., £14.00/\$27.35 0.12.085950.5

During the last fifteen years automated elemental organic analysis has expanded to such an extent that it has almost superseded manual operations, for certain elements at least. The purpose of this book is to bring together the accumulated knowledge and experience of investigators who have been dealing first hand with these new methods. To provide some flexibility, two different commercial apparatus for the determination of carbon, hydrogen, nitrogen and oxygen, have been described — the Perkin-Elmer and the Carlo-Erba apparatus. A comprehensive account of the applications of the Dohrmann coulometric apparatus has been included and also the remarkably efficient Merz-Dumas method. The latter is extraordinarily versatile in its applications, for it can cope with trace amounts of nitrogen as well as high percentages.

## Oxalic Acid in Biology and Medicine

A. Hodgkinson

December 1977, xiv + 360pp., £15.80/\$30.25 0.12.351750.8

This comprehensive review of oxalic acid in living systems brings together for the first time work in several fields, including analytical chemistry, microbiology, plant physiology, toxicology, nutrition and human pathology. The book is intended to be a source of reference as well as a guide to current research. Dr. Hodgkinson traces the role that oxalic acid has played in the development of early chemical theory, describes the structure and properties of the acid, and examines the problems of determining oxalate in biological material. A variety of topics of current interest is covered, including the role of oxalic acid in plant metabolism, the growing problem of livestock poisoning by oxalate-containing plants, and the problem of human poisoning by agents such as xylitol and methoxyflurane.

## Annual Reports on NMR Spectroscopy Volumes 6C and 7

Volume 6C edited by E. F. Mooney

December 1977, xiv + 658pp., £33.50/\$65.50 0.12.595347.9

Volume 7 edited by G. A. Webb

November 1977, x + 300pp., £16.00/\$31.25 0.12.505307.X

Over recent years no other technique has grown to such importance as that of NMR spectroscopy. It has applications in all spheres of science concerned with the electronic and molecular structures of materials as well as those areas concerned with the reactivity of molecules in solution. Progress has occurred in both the experimental and theoretical aspects of NMR. These are reviewed in this series and presented in a manner suitable for chemists from all disciplines. *Annual Reports on NMR Spectroscopy* is well established as a medium for communicating recent progress in NMR and its applications to the specialist and non-specialist alike. The series is a vital source of information for workers in all branches of chemistry; including biochemistry and pharmaceuticals, and will continue to be a valuable source of information for all analytical, structural and physical chemists.

### Contents of Volume 6C

P. W. Hickmott, Michael Cais and A. Modiano: NMR data on organic-metal carbonyl complexes (1965-1971)

### Contents of Volume 7

R. Fields: Fluorine-19 NMR spectroscopy of fluoroalkyl and fluoroaryl derivatives of transition metals, M. Witanowski, L. Stefaniak and G. A. Webb: Nitrogen NMR spectroscopy. Roderick E. Wasylishen: Spin-spin coupling between carbon-13 and the first row nuclei.

## Monographs of the Physiological Society No. 34

**Corticospinal Neurones**

## Their role in movement

C. G. Phillips and R. Porter

December 1977, xii + 448pp., £16.80/\$32.35 0.12.553950.9

This book is more than just a compilation of experimental findings. By discussing their personal observations in the context of accumulated knowledge the authors have produced a classic work which will endure long after new research has outdated parts of its findings. It reviews and analyses all major work on the corticospinal tract, starting with extensive historical material and terminating with newly published work. The strength of this analysis derives from one or other of the two authors having been personally engaged in most of the types of work described.

## London Mathematical Society Monographs No. 10

Series editors: P. M. Cohn and G. E. H. Reuter

**Topos Theory**

P. T. Johnstone

December 1977, xxiv + 367pp., £17.50/\$34.25 0.12.387850.0

Since the pioneering work of F. W. Lawvere and M. Tierney in 1969 and 1970, topos theory has been one of the major growth areas of mathematics: in particular, it has been characterized by the development of striking new links between algebra, geometry and logic, whereby the methods used in each of these areas may be applied to problems in the others. This book is largely based on lectures and seminars given by the author at the Universities of Cambridge, Liverpool and Chicago, and is the first comprehensive account of these developments to be published.

**Surface Carbohydrates of the Prokaryotic Cell**

edited by I. W. Sutherland

December 1977, x + 472pp., £19.50/\$38.00 0.12.677850.7

This publication provides a current view of the composition, biosynthesis and control of the surface carbohydrates of prokaryotes, superseding earlier reviews in this rapidly expanding field. These aspects are related to the possible functions of the polymers and to their role as receptors for bacteriophage and as antigens or haptens. Enzymes degrading the polysaccharides are also considered and the information they provide about polysaccharide structure is discussed. The author indicates the direction of current research in the field, problem areas, and recent improvements in technique. *Surface Carbohydrates of the Prokaryotic Cell* will be of primary value to undergraduates, research students and workers in microbiology, biochemistry and related fields.

**A World Geography of Human Diseases**

edited by G. Melwyn Howe

December 1977, xxx + 622pp., £24.00/\$46.90 0.12.357150.2

Professor Howe's book deals with the main diseases of mankind on a global basis, bringing together a group of leading experts whose approach is varied and multi-disciplinary, but who share a particular interest in the problems of man's interaction with his environment, and in the global variability and spatial patterning of disease. Suffering and death have a multitude of different causes, but the diseases selected for this volume certainly account for a major share of the world's sixty million deaths annually. The text demonstrates the intricate links between physical, biological, socio-cultural and lifestyle hazards and the different causes of illness and mortality.

**Kidney Hormones**

## Volume II Erythropoietin

edited by J. W. Fisher

December 1977, xvi + 602pp., £24.00/\$46.90 0.12.257652.7

This second volume of this three part series on kidney hormones deals exclusively with the production of erythropoietin and the nature of erythropoietin itself, a renal hormone that has been clearly identified and characterised only during the past 10-15 years. Many aspects of erythropoietin are covered: the history of the development of erythropoietin and humoral control of erythropoiesis; physico-chemical characterization and isolation procedures for erythropoietin; pharmacology and physiology of erythropoietin; erythropoietin production in disease states in man; and the implications of erythropoietin for clinical usage.

# How Britain runs its science

This highly successful chart, which appeared in *Nature* 28 August 1975 (but is still much requested and much referred to), has now been completely revised and updated to include all major changes in the personnel and administration of British science.

Measuring approximately 2' x 3' and containing black-and-white illustrations of prominent figures, copies of this chart are now available at 75p (UK), US \$1.50 (Rest of World).

Payment may be made in any currency at the prevailing exchange rate. Cheques should be made payable to Macmillan Journals Ltd. Prices include postage and packing.

To order please complete the coupon below, or write, enclosing the correct remittance.

*coli*) or eukaryotic origin (such as yeast, frog or *Drosophila*). The UK Genetic Manipulation Advisory Group (GMAG) is currently insisting that all unrecognised DNA fractions from shotgun experiments should be destroyed rather than preserved in collections, as is apparently the case for such libraries in other countries. This seems to underline the necessity of seeking international agreement, as indeed, ICSU, ESF, EMBO and WHO are trying to work towards on issues such as these. There can never be a case for seeking a general code of conduct for handling genetic recombination experiments, but the *principles* could well be agreed. Among these is the amassing

that might be discovered. For industry in the UK and even for academic workers, there is, however, a strong disinclination to declare plans and objectives to GMAG in the detail required. How this problem of confidential treatment will be resolved remains to be seen.

Sydney Brenner, who figured prominently in the Asilomar discussions—often apparently coming to the rescue when a particular meeting seemed to have been stalled—seizes an opportunity to advance the concept of a “disarmed bug”—biological containment to supplement physical containment which Paul Berg (p151) had condemned in a letter, as “overrated and,

they will even try to understand all the issues at stake. Will it be enough that the UK watchdog, the Health and Safety Executive, reinforces the advisory group (GMAG)? The public does, indeed, have four representatives on GMAG together with ASTMS, IPCS and TUC union members.

Public opinion may well be satisfied in the UK that laboratory manipulations are carried out safely in inspected premises (for the two higher containment categories). Are the US public so satisfied? No, they are not. According to Rogers, they do not trust the scientists, judging them to be mere self-servers, anxious to gain instant recognition and credit at the expense of the public and, moreover, encouraged and supported by the NIH which is largely composed of a peer group with identical motivation. Normally, the older generation is more conservative than the younger. This issue has converted the younger in the US into “nay-sayers”. The “yay-sayers” are their elders.

The scientific debate has elicited a response from the law-makers in the US and a counter-response from the scientists. It seemed, until recently, that a Federal law would be passed regulating the issues. The scientific community does, however, seem to be gaining the upper hand. If this opens the way for States to enact their own rules, Mayor Velluci for one will, no doubt, be satisfied. There will be some States who will be strict and some not so strict. In which will the experiments tend to get done? There is already a strong ground swell in the US in favour of relaxing the NIH's guidelines. After all, nothing has yet happened to create an ecological disaster, has it? the disarmed hosts/vectors that we currently have, seem to be more than adequate; Nature may even have tried many of the scientists' new tricks without the benefit of guidelines. Well, the pendulum was bound to begin the reverse swing somewhere, soon. I hope that a sensible mid-position can be found, and held.

This book sounds the occasional wrong note but it tells an interesting story of the US honestly and well, warts and all. An index would have been useful. The UK has only a passing reference (to GMAG) at the very end where the guidelines are damned with faint praise—“probably generated considerable scientific red tape”. Coloured, perhaps, by Rogers' rose-tinted spectacles? □

R. J. C. Harris is Director of the Microbiological Research Establishment at Porton Down, UK, and a current member of the Genetic Manipulation Advisory Group.

Paul Berg (left) and David Baltimore (right)

Photos: NAS (Berg) and Noëleen Chedd (Baltimore)

of “libraries” from shotgun experiments, since, in the present state of genetic knowledge, the dangers of accumulating unknown, as well as known and recognisable, dangers, are not insignificant. Very well, these dangers are only potential, not actual. The public is unlikely to be impressed by such an argument. Wisdom after the event cannot be entertained.

The book contains an outline of many problems, but the solutions to very few, despite the author's recourse to the (recorded) wisdom of the experts. American industry, for whom the NIH guidelines are politically inhibitory, was particularly worried about two aspects; first, the maximum 10-litre scale proposed and, second, the necessity to declare to other research groups any safer host-vector system

while reassuring to the psyche, is hardly the line of defence . . .”. Since Berg lists “careless mouth pipetting” as a cause of breakdown of physical containment apparently in a very high category, the training and discipline of those who are to work in such laboratories obviously leaves an enormous gap to be filled. “The ideal safeguard”, wrote Berg (according to Rogers), “is ingeniously designed biological containment that can prevent escape and propagation—even with slobos doing the work on open benches”.

Yet another of the problems facing NIH's Advisory Committee on Recombinant DNA Molecules is simple enough to define. Scientists can hope to understand, and reason with each other; but where will the public stand? It is not to be expected that

# Molecular politics for novices

Sydney Brenner

*The Ultimate Experiment: Man-Made Evolution.* By Nicholas Wade. Pp. 162. (Walker: New York, 1977.) \$8.95.

A VAST LITERATURE has accumulated in the few years since the issue of recombinant DNA research made its appearance. The documents in the case already fill several shelves, and there seems to be no end yet in sight. What began as a laboratory technique followed by some doubts expressed by scientists quickly generated a worldwide debate which spread over an enormous range of scientific and social questions. Molecular biologists were thrust into an arena very different from their laboratories and found themselves embroiled in discussions first with clinical microbiologists and safety engineers and then with lawyers, philosophers and politicians, trying to solve what in many cases were, and still are, insoluble problems. The debate was played out on the public stage, often with all the actors in full frontal nudity, so that what began as domestic drama soon took on, as Jim Watson put it, "the aspects of a black comedy".

Indeed, there were times when one came to believe that the real issue at stake was human rationality; and the new subject of "molecular politics" still demands a fine sense of the ludicrous.

Nicholas Wade has now written a book to help the ordinary reader through the tangled maze. He gives a simple account of the techniques used to join DNA molecules together, to introduce the beginner in molecular biology to the world of restriction enzymes, plasmids and shotgun experiments. Here too, one will find explained physical and biological containment. But more important than this technical background is that the novice in politics will get a clear idea of the development of the issue, from its beginnings at the Gordon Conference in 1973, when concerns about the research were first formally expressed, right up to the recent debate in the US on legislative means for regulating work on recombinant DNA. As readers of his articles in *Science* will know, Nicholas Wade attended most of the meetings that were held, and he is able to communicate something of the atmosphere of the debate, particularly as it has evolved in the US. There, as some of the foreign scientists who attended the Asilomar Conference discovered to their horror, the Press attend meetings organised by Federal agencies. At Asilomar, it became clear that their presence would ensure that not only the content but also the style of the argument would be relayed to the outside world. The sole public

objector to the Press at the meeting, when asked to explain his behaviour by an irate journalist, remarked that he "believed in the inalienable right of consenting adult scientists to make fools of themselves in private". That exchange with a man who represented a newspaper that had brought about the downfall of the President of the country together with the fact that two-thirds of the participants were American, led to the perception that the discussion of the issue would be strongly affected by the political and scientific conditions of the US. As the book clearly shows, time has proved this to be correct. The action is set firmly on the American stage and there are only passing references to what was going on in the UK and other countries. True, very little was happening and then only on a more subdued level; but there can be no doubt that the Ashby Report was an important element in helping the Asilomar Conference to decide what work should be done.

The book can only be comprehended in the context of American society. We must remember that the issue arose at a time when the Watergate episode had suspended trust in governmental institutions, when the radical university movement had lost its focus with the end of the Vietnam war, when the honeymoon between pure science and government had ended, and when, even in the US, resources had become limited. Only these crude facts and not abstract principles can explain such bizarre events as the alliance between the radicals in Cambridge, Massachusetts, and the Mayor of that town.

The reader will quickly find that the debate abounds with difficulties and paradoxes. Take the argument advocated by Sinsheimer and Chargaff that new artificial recombinants could generate an evolutionary catastrophe. This raises a deep scientific question which cannot be dismissed simply by Chargaff's reference to "the evolutionary wisdom of the past million years". We have to ask whether change in the biological world is limited by the extent of genetic variation or by selective pressure. It is this question which lies at the heart of the debate, and it cannot be avoided.

In our own time, an immense change has been wrought in the microbes associated with Man and animals. The enormous increase in antibiotic-resistant bacteria cannot be ascribed to the creation of novel recombinants out of nothing, but, as everybody knows, has been the direct outcome of the widespread and often indiscriminate use of antibiotics. The genetic elements conferring penicillin resistance must have existed before the discovery of penicillin; they were enriched because

Tenth Edition

**\* IMMS' GENERAL TEXTBOOK OF ENTOMOLOGY**

Edited by O. W. RICHARDS, F.R.S. and R. G. DAVIES

The new edition of this standard reference text, covering all aspects of entomology, has been revised and extensively rewritten, reflecting the broader scope of entomology today, while retaining the features responsible for its renown. The new edition has been expanded to such a degree that it has been decided to publish it in two volumes:

Volume One – Structure, Physiology and Development  
Volume Two – Classification and Biology

**VOLUME ONE: STRUCTURE,  
PHYSIOLOGY AND  
DEVELOPMENT**

10th November 426 pages  
Hardback 412 15200 2 £15.00  
Science Paperback 412 15210 X £5.95

**INTRODUCTION TO  
BIOMETRICAL GENETICS**

K. MATHER, F.R.S. and J. L. JINKS, F.R.S.

An up-to-date account of the subject designed especially for university students, whether senior undergraduates or others who have discovered the need for understanding continuous variation. The book shows how genetic models are formulated and tested, how the necessary parameters are estimated and interpreted and how the experiments are designed. *Introduction to Biometrical Genetics* is comprehensively illustrated by numerous examples taken from plants, animals and man.

October 240 pages  
Hardback 412 15310 6 £8.50

**\* THE EEL**

Biology and management of anguillid eels  
F. -W. TESCH

'This is a solid work on the scientific and commercial biology of the eel.' So wrote a reviewer of the original German edition in the *Quarterly Review of Biology*.

In this first English-language edition, the content has been updated throughout, and the sections dealing with physiology, anatomy and classification have been completely rewritten.

The text covers all aspects of the natural history of the genus *Anguilla* with especial emphasis on the ecology, reproduction, migration, physiology, fishery management, fishing techniques and fish farming.

24th November 408 pages  
Hardback 412 14370 4 £18.00

**VOLUME TWO:  
CLASSIFICATION AND  
BIOLOGY**

10th November 952 pages  
Hardback 412 15220 7 £30.00  
Science Paperback 412 15230 4 £15.00

**\* INTRODUCTION TO HIGH  
PERFORMANCE LIQUID  
CHROMATOGRAPHY**

R. J. HAMILTON and P. A. SEWELL

*Introduction to High Performance Liquid Chromatography* has been carefully prepared to act as a coherent guide to the principles and practice of the technique for all those chemists, biochemists and pharmacists and students, who are learning about or who are actually using this increasingly valuable method of analysis.

October 196 pages  
Hardback 412 13400 4 £8.00

**\* HANDBOOK OF AIR  
POLLUTION ANALYSIS**

Edited by R. PERRY and R. YOUNG

The primary object of this book is to provide a comprehensive and practical manual on the best methods for the location, analysis and monitoring of atmospheric pollution. The contributors are drawn from a wide range of backgrounds and write from extensive personal experience on all these aspects catering for new workers in the air pollution field and also for others involved in the more specialized areas of research.

10th November 528 pages  
Hardback 412 12660 5 £20.00

**COLD SPRING HARBOR LABORATORY**  
P.O. BOX 100, COLD SPRING HARBOR, NEW YORK 11724

# REPLICATION OF MAMMALIAN PARVOVIRUSES

EDITED BY **David C. Ward**, Yale University  
**Peter Tattersall**, Imperial Cancer Research Fund  
Mill Hill Laboratories

This book brings together the current knowledge, experiments, and hypotheses from the exciting and rapidly expanding field of mammalian parvovirus research. This comprehensive collection of review and original research articles covers in depth the unique physical and biological properties of this family of ultrasmall, possibly monogenic viruses and outlines some of the intellectual challenges still to be resolved.

This book should provide fascinating reading for virologists, pathologists, molecular biologists, and all those interested in genome structure, mechanisms of DNA replication and gene expression, and virus-host interactions during development and neoplastic transformation.

MVM maturation (Richards et al.)  
In vitro assembly of Lull (Gautschi et al.)  
Intracellular nucleoproteins of KRV (Gunther and Revet)  
EM of H-1 intracellular development (Singer and Rhode)  
Heavy and light infectious forms of H-1 (Kongsvik et al.)

## Appendix

A standardized nomenclature for restriction endonuclease fragments

# DNA INSERTION ELEMENTS, PLASMIDS, AND EPISOMES

## EDITED BY

**A. I. Bukhari**, Cold Spring Harbor Laboratory  
**J. A. Shapiro**, University of Chicago  
**S. L. Adhya**, National Cancer Institute

Capturing the excitement of the discovery of this new class of genetic elements—DNA insertions—and detailing the extraordinarily varied facets of insertion phenomena, this book stands alone as the first complete treatment of these new pathways for the reassortment of genetic information and the evolution of chromosome structure in both higher and lower organisms.

**1977, 796 pp., illus., index ISBN: 0-87969-118-2**  
**\$36, clothbound**

Nomenclature of Transposable Elements in Prokaryotes  
Section I: IS Elements  
Section II: Transposons and Plasmids  
Section III: Bacteriophage Mu: A Transposable Element  
Section IV: Nonhomologous Recombination and the  $\lambda$  Paradigm

Section V: Eukaryotic Systems  
Section VI: Genetic Rearrangements; Techniques and Applications  
Appendices: The eleven appendices to this volume contain detailed information, including complete bibliographies: List of IS elements and their properties; sequences for IS2; plasmids found in *E. coli*, *Pseudomonas*, *S. aureus*, other gram-positive bacteria and plasmids constructed in vivo and in vitro (their molecular weights, number of copies per cell, etc.); the genomes of temperate phages (molecular weights, intracellular forms, integration sites, etc.); restriction endonucleases (a complete list with recognition sequences); physical (endonuclease cleavage) and genetic maps of temperate bacteriophages  $\lambda$ , P1, P2, P22,  $\phi$ 80, and Mu; methods for cultivation and use of Mu.

our technology produced an enormous increase in the concentration of this chemical in the world. Natural mechanisms of recombination ensured that these would spread, given the selective pressure exerted. Thus, it could be argued that mere existence is not enough, even survival is not enough; for any element to come to dominate the world there must also be a strong selective advantage and the means for its transmission. It is not widely realised that the Western region of the US is one of the world epicentres of plague, yet this is patently not a serious disease in that country. The reason is not that every plague bacillus in California is securely locked up in a P4 facility but simply that the environmental structure of a modern civilised society is incompatible with the selective propagation of that organism.

These and other issues are still with us, and the story is by no means ended. Yet, in looking back over the past three or four years something positive has been accomplished. The research work

has been allowed to continue, perhaps at a slower pace than many people hoped for; it is the results that are now beginning to emerge that will bring the greatest justification when the tumult has quieted and the dust has settled; and what will remain for the historians of the future will be the insights the technique will have given into the structure of genes in higher organisms. Whether or not any of the other benefits promised by some molecular biologists will have become realised is hard to say. When they appear, however, it will be society and not science that will be judged, because some of us will then want to know whether these benefits are to be used for the good of all humanity or merely to satisfy the selfish interests of some industrial societies. □

*Sydney Brenner is Head of the Division of Cell Biology at the MRC Laboratory of Molecular Biology in Cambridge, UK, and will become Director of that Laboratory in 1979.*

## Rational agriculture

J. G. W. Jones

*The Famine Business.* By C. Tudge. Pp. 141. (Faber and Faber: London; St Martin's: New York, 1977.) £3.95; \$8.95.

In writing about the future of world food supplies, authors are often tempted by one of two easy options: first, optimism that resources will be found to enable mankind to maintain the *status quo*, which in many respects is inequitable and dangerous for large groups of the World's people; or, second, total disaster which could only result in global famine and a massive reduction in population through starvation. Mr Tudge avoids both these extremes and charts a much more difficult course for food production.

He introduces his subject by assailing the myths of population, energy use, and aid to developing countries; there can be no repetition of the economic growth experienced by the Western World since the Industrial Revolution nor a solution to the problems of feeding the developing nations based on technologically advanced agriculture. On the one hand he rejects the idea of the "world farm", where each area of the world specialises in growing what it is best able to, and on the other the idea of national self-sufficiency. The solution he proposes is one of "rational

agriculture" which, considering the difficulties, he defines remarkably precisely as "one that makes best use of the land, while meeting the nation's nutritional needs and gastronomic aspirations." The physical organisation proposed consists of (a) regional specialisation to a degree for beans, cereals and potatoes, and (b) local self-sufficiency for fruit and vegetables together with pigs and poultry fed on plate wastes. Establishing a rational agriculture would be impossible in capitalist systems but what kind of political and economic framework would be best is not stated. Capitalism is excluded on the grounds of its need for continuously expanding economies which are not sustainable in relation to food supplies unless irrational buffers, such as meat production from cereals or food processing, are introduced.

In discussing the nutritional implications of rational agriculture, the author asserts that man has always been omnivorous; any imbalance towards carnivorousness or herbivorousness is due to the omnivorous man's capacity to adapt to circumstances, and especially to the commercial promotion of meat, since the Industrial Revolution. The protein myth is predictably debunked. A plea is made to use the peasant cuisines of the World which were based on austerity and evolved to make palatable and interesting dishes.

The food processing industry is attacked as being concerned with unnecessary operations designed "to impose industrial techniques on food production". Many of its claims are quite contrary to the facts; variety,

seasonality and localisation of food supplies are all lost. Is "convenience" really achieved when time and energy is spent on distant marketing at hypermarkets rather than in the kitchen cooking? Particularly adverse comment is levelled at what Tudge calls "ersatz" foods. The price of meat analogues should be compared with the price of the beans from which they are made rather than with the price of meat; it would then be seen that not only are they inefficient in the use of resources but also uneconomic from the consumer's point of view. The industrial production of single-celled proteins is technologically too advanced for the Third World, and when all is said and done is only suitable for animal feed and thus inefficient.

The book cannot be described as cranky. It is logical and engaging to read, and, except in his attacks on the food processing industry, the author is commendably restrained in his consideration of the implications of rational agriculture for technology and for capitalism. Politics, nutrition and commerce have been mixed with iconoclasm to produce a book which should appeal to the idealist in every reader.

*J. G. W. Jones is Senior Lecturer in the Department of Agriculture and Horticulture of the University of Reading, UK.*

## Curriculum change and social climate

Mary Waring

*Science Textbook Controversies and the Politics of Equal Time.* By D. Nelkin. Pp. xi+174. (MIT Press: London, Cambridge and New York, 1977). £9.10; \$12.95.

In 1969, the Californian State Board of Education's guidelines for school biology ruled that creation theory, as given in Genesis, be taught as a viable, scientific alternative to the theory of evolution, equal time being accorded to both. The target was, clearly, National Science Foundation-funded BSCS texts, with their evolutionary underpinning, and the ruling represented a victory for local creationist pressure groups. Attacks on evolution were nothing new, and biologists responded only slowly; eventually, however, legal and political strategies seemed to be restoring the situation. Then, a nationally-linked network of creationist activists turned their attention to a NSF-funded social science

course, *Man: A Course of Study* (MACOS), whose evolutionary underpinning was far more explicit in its use of animal behaviour to develop concepts about the nature of man, and which fostered ideas of cultural relativism. The course had already received wide acclaim and, by 1974, was being used in some 17,000 schools in 47 states. In 1975, however, after several local controversies, and following Congressional airing of the issue, funds for MACOS were terminated, sales plummeted, and a major re-evaluation of the NCF's (federal) funding of science curricula was instituted.

The causes and effects of action can never be explained in their own terms, but only in relation to all the events—and the network of interests, vested or otherwise—of which the action is part. Clearly, creationists were merely catalysing processes already latent in American society, and Professor Nelkin therefore sought for more widely-dispersed social and political tensions. Her interest had been aroused initially by the fact that creationists were representing themselves as *scientists*, a claim that enabled them, in attacking science textbooks, to circumvent dismissal on grounds of irrelevance or of infringement of academic freedom. Moreover, their focus on the highly sensitive area of the role of schools in value transmission enabled them to capitalise on a seemingly widespread concern over the erosion of traditional moral and religious values. Other significant tensions were concern for the control of hitherto 'unaccountable executive bureaucracies', for a questioning of scientific 'authority', and for lay participation in decision-making.

Professor Nelkin's account makes fascinating reading and her analysis is valuable in drawing attention to the significance of social climate in educational decision-making, but it is not entirely satisfactory. This is, perhaps, partly because boundaries have to be drawn somewhere (the area is a very complex one), but it is also because there is some woolliness in the discussion of, for instance, the nature of science and, in particular, the relationships between the sciences (especially when social sciences are included), and of the standing of evolutionary theory. The fact that MACOS is in fact intentionally directed towards the development of judgement and tolerance in a pluralistic, democratically orientated society is not made clear in her concern to juxtapose scientific and social values, and we get no explanation for social scientists' failure to defend their project. (Biologists do not seem to have regarded it as their concern.) Curiously, too, no mention is made of the possible influence of economic recession on both sales and funding.

Nevertheless, there is a mine of information and careful documentation here. The story is well told and is absorbingly interesting. The book is a most useful addition to the literature on curriculum change and social

climate and on pressure groups in science education. □

Mary Waring is Lecturer in Education (Social Biology) at the Centre for Science Education, Chelsea College, University of London, UK.

## Policy research perspectives

Stuart S. Blume

*Science, Technology and Society: A Cross-Disciplinary Perspective*. Edited by Ina Spiegel-Rösing and Derek de Solla Price. Pp. 607. (International Council for Science Policy Studies: London and Beverley Hills, California, 1977.) £20.

THIS volume offers a 'state of the art' review of that somewhat diffuse research field called here Science, Technology and Society (STS) studies, directed "mainly toward scholars in the various constituent sub-fields" (p3). Because the structure and value of the book can only be understood, and its strengths and weaknesses assessed, in the light of some appreciation of the structure of the field, I must begin with some general remarks on the study of scientific activity.

Research which the reviewer may choose to subsume under a heading such as STS in order to explore or (as intended here) to stimulate the 'intellectual integration' of the field is actually carried out from a variety of perspectives. Thus, sociology of science and the economics of research and development are both central, but most people working in these areas owe their principal allegiance to, and derive their research perspectives from, the well-established disciplines of sociology and economics. At the same time, there has emerged in the past 10–15 years a substantial multidisciplinary research activity, to which the existence of (for example) the Science Policy Research Unit at Sussex University, the Science Studies Unit at Edinburgh, and the Society for Social Studies of Science all bear witness. The fact is that the rapid growth, and institutionalisation, of both disciplinary and multidisciplinary research has not resulted in any real crystallisation of the field.

On the face of it, this apparently transitional intellectual structure has many parallels. Many new fields of scientific or technological research pass through phases in which some new integrative perspective competes, intellectually and professionally, with its parent disciplines. The early days of, for example, molecular biology, oceanography, radio astronomy, and materials science were like that. STS in fact differs from these in that 'the' new multidisciplinary perspective, which

ought to provide the basis for a new crystallisation, is itself fragmented. Broadly speaking, one nucleus has been science policy: the practical problems of allocating resources to science, organising research, stimulating and evaluating technological innovation, and so on. (Salomon's chapter in the volume under review shows how science policy research has been, in part, a response to the development and politicisation, of national science policies.) Equally broadly, a second nucleus has derived from the growing conviction among (some) historians, philosophers, and sociologists of science that the production of scientific knowledge has to be seen as having both epistemological and social dimensions which in fact interact. Thomas Kuhn's famous book *The Structure of Scientific Revolutions* was a major stimulus to this recognition of the need for cooperation.

What we have today, therefore, is a considerable variety of research approaches, and related problems and priorities, some of which (and these far from dominant) imply the need for greater cooperation between two or three relevant disciplines. For example, in addition to a perspective which relates sociologists, philosophers and historians of science, another begins to link economists and political scientists in the study of technological change.

In grouping their contributions into three sections, Ina Spiegel-Rösing and Derek Price have made a similar kind of categorisation of orientations to the field. The first section, seeking to be integrative, focuses mainly on the origins, institutional structure and cognitive structure of STS as 'a' subject. The second section looks at the achievements of social studies of science, taking the relevant disciplines *seriatim*, whereas the final one considers science policy-related studies, and is mainly written by political scientists. Because part 1 is closely bound up with the scope, utility, and future of the subject as a whole I will postpone discussion of it for the moment.

Part 2 contains chapters by a sociologist, two historians (of science and of technology), an economist, a psychologist, and a philosopher. One turns to these chapters with numerous hopes: of an outline of the various perspectives current in each discipline, their achievements, and their potentialities (especially for greater cooperation with other disciplines); and of some communication of the excitement of the research and of its currently crucial problems. Although some contributors (notably Fisch on

**Announcing**

# **GAMETE RESEARCH:** an international journal devoted to animal and plant sex cells, fertilization and early development

Edited by Ralph B. L. Gwatkin, Merck Institute for Therapeutic Research  
P. O. Box 2000, Rahway, NJ 07065

This new journal is devoted to increasing understanding of reproduction, cell surfaces, cell-cell interaction, growth and development, infertility, and new contraceptive technology. Specific topics include:

- animal and plant breeding
- genetic engineering
- gamete transport
- preservation of eggs and sperm by freezing
- in vitro fertilization and embryo culture
- artificial egg activation
- gamete membranes and receptors
- parthenogenesis
- sex determination
- nuclear transportation into eggs
- artificial insemination

**First Issue To Be Published Spring 1978**

Volume 1, 1978, Four Issues \$55.00

## **Journal of Medical Virology**

Edited by Arie J. Zuckerman, Department of Microbiology,  
London School of Hygiene and Tropical Medicine,  
Keppel Street (Gower Street), London WC1E 7HT, England

Journal of Medical Virology publishes major developments and reviews important progress in all aspects of medical virology: structure and composition of viruses, epidemiology, diagnosis, humoral and cell-mediated immune response, pathology, clinical features of infection, and treatment and prevention.

Volume 2, 1978, Four Issues \$35.00

## **American Journal of Medical Genetics**

Edited by John M. Opitz, Clinical Genetics Center,  
University of Wisconsin-Madison, Madison, WI 53706

American Journal of Medical Genetics publishes original research findings in the biology of genetic and congenital diseases in man. The journal also publishes reviews, case reports, editorial essays, and announcements.

Volume 1, 1977/78, Four Issues \$45.00

**ALAN R. LISS, INC.** Scientific, Medical and Scholarly Publications

# OUTSTANDING

## BIOLOGY AND BIOMEDICAL RESEARCH

*Selected in 1977 as  
the Best Book on a Medical Subject for Physicians  
by the American Medical Writers Association*

### **Viral Infections of Humans** Epidemiology and Control

edited by **Alfred S. Evans**  
Yale University

"... recommended highly as a reference for those involved in microbiology or virology courses for medical students and should be a part of any medical or public health school library."  
—*American Society for Microbiology News*

584 pp., illus., 1976, \$47.40/£24.89

### **The Science of Photobiology**

edited by **Kendric C. Smith**  
Stanford University School of Medicine

This new book—the first comprehensive textbook in the field—authoritatively examines each of the fourteen subspecialty areas of photobiology as designated by the American Society for Photobiology. 431 pp., illus., 1977, \$42.00/£22.05 hardcover, \$15.00/£7.88 softcover

### **Immunopharmacology**

edited by **John W. Hadden** and **Ronald G. Coffey**  
Sloan-Kettering Institute for Cancer Research  
and **Federico Spreafico**

"Mario Negri" Institute for Pharmacological Research

Provides extensive information on experimental pharmacologic modulation of cellular immune response, the roles played by cyclic nucleotides, and applications in anti-inflammatory, anti-allergic, immunosuppressive, and immunopotentiator therapies. *Comprehensive Immunology*, Volume 3. Series Editors: **Robert A. Good** and **Stacey B. Day**. 423 pp., illus., 1977, \$42.00/£22.05

Not available from Plenum in Japan and Okinawa.

### **Advances in Microbial Ecology**

edited by **M. Alexander**  
Cornell University

In recognition of the emergence of microbial ecology as a growing and independent discipline, this series is devoted to the examination of diverse ecosystems and processes among all major categories of microorganisms.

Volume 1: 268 pp., illus., 1977, \$29.40/£15.44

### **Regulation and Genetics: Viral Gene Expression and Integration**

edited by **Helnz Fraenkel-Conrat**  
University of California at Berkeley  
and **Robert R. Wagner**  
University of Virginia

Focusing on RNA and DNA viruses, this volume deals with modes of integration of tumor viruses into host cell genomes and the nature and role of defective interfering animal virus particles. *Comprehensive Virology*, Volume 10. 496 pp., illus., 1977, \$47.40/£24.89

### **Photochemical and Photobiological Reviews**

edited by **Kendric C. Smith**  
Stanford University School of Medicine

"The reviews themselves are lucidly written, critical as well as descriptive, giving both historical perspective and an up-to-date report of the literature ... the new series will provide a valuable reference source for researchers and students interested in the interaction of light and living matter."

—**Barbara A. Zillinskas**, *BioScience*

Volume 1: 391 pp., illus., 1976, \$39.00/£20.48

Volume 2: 329 pp., illus., 1977, \$35.40/£18.59

Volume 3: approx. 265 pp., 1978, price not yet set

### **Identified Neurons and Behavior of Arthropods**

edited by **Graham Hoyle**  
University of Oregon at Eugene

Dedicated to Professor C. A. G. Wiersma's pioneering work with crustaceans, this historic new book provides the only comprehensive summary of the latest research on the cellular basis of behavior in arthropods.

approx. 590 pp., illus., 1977, \$47.40/£24.89

### **Nutrition, Immunity, and Infection** Mechanisms of Interactions

by **R. K. Chandra**  
Memorial University of Newfoundland  
and **P. M. Newberne**  
Massachusetts Institute of Technology

Provides a concise, critical summary of the most recent research findings on the relationships among diet, morbidity, and mortality, and assesses the limitations and significance of the pertinent literature published up to and including 1977.

approx. 235 pp., illus., 1977, \$27.00/£14.18

# TITLES FROM PLENUM

## CHEMISTRY

### Contemporary Topics in Analytical and Clinical Chemistry

edited by **David M. Hercules**  
University of Pittsburgh

**Gary M. Hieftje**  
Indiana University

**Lloyd R. Snyder**  
Technicon Instruments Corporation

and **Merle A. Evenson**  
University of Wisconsin

The series includes articles on current analytical techniques and state-of-the-art advances in related areas of importance.

**Volume 1:** 327 pp., illus., 1977, \$30.00/£15.75

*New and enlarged edition*

### Salt-Water Purification

by **K. S. Spiegler**  
University of California, Berkeley

Provides a basic introduction to the science and technology of the desalting process; including reverse osmosis (hyperfiltration), economic factors regarding equipment and materials, and alternate methods of securing an adequate water supply.

189 pp., illus., 1977, \$23.40/£12.29

### The Chemical Physics of Surfaces

by **S. Roy Morrison**  
Stanford Research Institute

"... a treasury of information and an essential acquisition for any laboratory engaged in surface studies involving catalysis and solid-gas or solid-liquid interactions, especially of semiconducting solids."

—**David Tabor, Nature**  
415 pp., illus., 1977, \$47.40/£24.89

### Transient Techniques in Electrochemistry

by **Digby D. Macdonald**  
Stanford Research Institute (SRI International)  
Using detailed descriptions, the author explains how the variety of currently available techniques may be used to analyze transient electrochemical processes.

329 pp., illus., 1977, \$45.00/£23.63

## OCEANOGRAPHY

### The Fate of Fossil Fuel CO<sub>2</sub> in the Oceans

edited by **Nell R. Andersen**  
National Science Foundation  
and **Alexander Malahoff**  
National Oceanographic and Atmospheric Administration

Significant for its exclusive concentration on a single major atmospheric pollutant, this book explores the serious consequences of the increasing injection of fossil fuel CO<sub>2</sub> into the oceans. Its effect on our atmosphere, climate, and environment are examined in depth. *Marine Science*, Volume 6.

749 pp., 1977, \$71.40/£37.49

### The Ocean Basins and Margins

edited by **Alan E. M. Nairn** and **William H. Kanes**  
University of South Carolina

and **Francis G. Stehli**  
Case Western Reserve University

This volume focuses on the geophysical and geological aspects of the lands within, and marginal to, the Mediterranean Sea, examining all available geophysical data, past tectonic features, and present depositional features on the neighboring coastal regions.

**Volume 4A: The Eastern Mediterranean:** 503 pp., illus., 1977, \$59.40/£31.19

## Oxford books - new and forthcoming

### Handbook of the Birds of Europe, the Middle East and North Africa

The Birds of the Western Palearctic  
Volume I: Ostriches to Ducks

Edited by Stanley Cramp  
and K. E. L. Simmons

Great advances have been made in ornithology in recent years, and research is now conducted on a wider geographical basis than in the past. This new *Handbook* is planned as a comprehensive and authoritative reference work for both the professional scientist and the amateur ornithologist. The seven volumes will cover all the 795 species of birds occurring in the area. Volume I covers the Ostrich; Divers; Grebes; Albatrosses; Petrels and Shearwaters; Storm-petrels; Tropicbirds; Gannets and Boobies; Cormorants; Pelicans; Frigatebirds; Bitterns; Egrets, Darters, and Herons; Storks; Ibises and Spoonbills; Flamingoes; Swans, Geese and Ducks. 56 colour plates. £25

### The Arthropoda

Habits, Functional Morphology  
and Evolution

S. M. Manton

The Arthropoda exceed in numbers of species the whole of the rest of the animal kingdom combined. Dr. Manton presents a review of the evolution and relationships of the Arthropoda, drawing upon half a century's intensive study of their functional morphology and on embryological studies. The numerous original illustrations are an important feature of the book. A classification of the Arthropoda is included, and technical methods are covered in a brief appendix. Illustrated £20

### Two-Phase Flow and Heat Transfer

Edited by D. Butterworth  
and G. F. Hewitt

Two-phase flow, in which the interface between the phases, usually gas and liquid, is influenced by their motion, is a phenomenon of importance in a wide variety of industrial plant, including boilers and nuclear reactors. The achievement of the maximum economy, efficiency, and safety requires quantitative information about the relevant fluid dynamics and heat transfer. This book covers gas/liquid two-phase flow, two-phase heat transfer, hydro-dynamic instability, and condensation, finishing with a discussion of loss-of-coolant accidents in nuclear reactors. £14 *Harwell Series*

### Physical Chemistry

P. W. Atkins

This completely new textbook of physical chemistry has been written as a basic course text suitable for college and university courses throughout the world, and will be the most complete and up-to-date textbook available. Its emphasis is on the explanation of concepts and on showing how qualitative physical ideas are turned into quantitative, testable theories. Special attention is paid to the simplification of conventional mathematical arguments, and to the explanation of their physical basis. Nearly 200 worked examples show how calculations are actually done. £15 paper covers £7.95

### Boolean-Valued Models and Independence Proofs in Set Theory

J. L. Bell

Since the discovery by P. J. Cohen in 1963 of the independence proofs for the Axiom of Choice and the Continuum Hypothesis, a vast amount of work has been done on the foundations of set theory. This book aims at a motivated account of some of the most important results. £5.95 *Oxford Logic Guides*

### Mathematical Cosmology

Peter T. Landsberg  
and David A. Evans

Cosmology is a subject of much scientific and philosophical interest, but accounts are usually either non-mathematical or fully relativistic. This book gives readers a quantitative understanding of some of the important aspects of general relativistic cosmology, starting only with school mathematics and Newtonian ideas in physics. It is concerned mainly with various models that have been proposed to explain the large-scale structure of the universe: the Friedmann models, steady-state models, and model universes involving pressure. £6.95

### Nonlinear Ordinary Differential Equations

D. W. Jordan and Peter Smith

This textbook in the qualitative theory of nonlinear differential equations is for students in mathematics or in mathematics-orientated combinations and is directed towards practical applications. There are over 400 examples and exercises in which a wide variety of mechanical, biological, and electrical applications appear. £12 paper covers £6.50 *Oxford Applied Mathematics and Computing Science Series*

**Oxford University Press**

psychology of science) are greatly handicapped by lack of progress to report, on the whole one is not disappointed.

MacLeod's chapter on the social history of science is particularly successful. He shows that this remains a minority perspective within the history of science, because it rejects the common assumption that scientific developments can be understood in terms purely of their intellectual antecedents, without reference to the environment of discovery. Moreover, for the social historian (though not for the orthodox 'internalist'), this environment is itself a subject of interest, providing potential linkages with other disciplinary perspectives. One turns the final page of MacLeod's chapter both informed and enthused.

Freeman (on the economics of R&D) and Mulkay (on the sociology of science) provide the highly professional treatments one expected. Freeman outlines the perspective on science and technology found in each major school of economic thought, from Adam Smith, and indicates the findings of recent empirical work on technological change. He devotes considerable space to the kinds of question which might lead to greater cooperation between economists and other specialists (for example, whether government investment in industrially orientated R&D should supplement or complement—in terms of industrial sector and timescale of benefits—what firms themselves do), and ends with a plea for a "political economy" of R&D.

Mulkay concisely summarises the major achievements of the sociology of science since R. K. Merton's pioneering work of the 1930s. He might only be faulted for saying too little about the frontier points at which sociologists are coming to work with philosophers on the one hand (partly treated by Böhme) and political scientists on the other.

There is considerable overlap in part 3 between Sapolsky (on science, technology and military policy), Schroeder-Gudehus (on foreign policy) and Skolnikoff (on the international system), although each writer offers valuable insights. I did feel the need, however, for some (even implicit) notion of the uniqueness and coherence of science and technology; more sociological understanding might have been helpful. An adequate understanding of the changing relationship between scientists and political power (treated by Lakoff) must involve appreciation of the effects of this relationship on the ethical and normative system of science, the constraints on the occupants of advisory roles, and so on. These are (partly) sociological questions.

Still more important, though seemingly unrecognised, is the need for some kind of theory of technological change. For example, Sapolsky makes the interesting observation (p458) that the process of weapons development may have become

'autonomous': "so oriented to serving its own internal needs that it weakens security by generating weapons which are too costly to produce" in sufficient quantities. Layton, writing about the history of technology, refers (p127) to demands for more socially responsive technology as requiring "a change in the inner structure of technology". But what is this "inner structure" and how does it change?

In Nelkin's chapter, we turn from the disciplines of the social sciences to the real world problems posed for policy-makers and citizens by modern science and technology. How can we make social assessments of technology? How can adversary (for example, court) proceedings cope with technical questions? When should we mount a giant "Manhattan Project" attack (for example, on cancer) and when should we more wisely invest principally in basic research? STS research has few answers here, and this has to be recognised in assessing the current usefulness of the field, and the book, to those who are concerned non-specialists.

I now return to part 1, which is most relevant to a general overview. It is certainly recognised here that the current state of STS research is not such as to throw much light on practical questions (other than in some very narrow areas). But part 1 should have gone further. These practical questions surely require,

as most practical questions do, an integration of insights of a multidisciplinary nature. It is clear from the book that in this field such integration, such crystallisation, has made little progress. And yet in many of the contributions one finds reference to problems and perspectives that promise or imply cooperation with other disciplines. The locus of these cooperative possibilities, which could have been traced out, might have served as a beacon to those wandering this terrain.

Some of those who work on STS will take pride in the achievements charted in this book. Others, among whom I include myself, are perturbed rather that so much has happened in so piecemeal, so incoherent a fashion. The vast creative effort which might have forged of this book a motor of real progress has not been made. Perhaps no-one could have done it, and the criticism is unfair. I can certainly say that anyone deriving sociological, economic, philosophical or policy research problems from science and technology should read the book. I cannot really recommend it more widely, and indeed I rather hope that my erstwhile science policy colleagues in Whitehall do *not* read it. It will not persuade them of the usefulness of this kind of work!

*Stuart S. Blume now works in the Department of Sociology and Psychology at Chelsea College, University of London, UK.*

## Utopian dream

Marie Jahoda

*Civilization in Crisis: Human Prospects in a Changing World.* Pp. 303. By J. A. Camilleri. (Cambridge University: Cambridge, New York and London, 1977.) £7.50 (paperback £2.50).

CAMILLERI, a young Canadian political scientist at Le Tobe university, has performed a *tour de force* in this book. He aims at nothing less than a comprehensive diagnosis of the many factors which account for the "decadence of industrial culture", to establish a "utopian vision" and to propose a "realistic strategy for change".

The major part of the book is devoted to the diagnosis of the current crisis which Camilleri regards as a crisis threatening the survival of man as a species. His arguments go, however, in scope and spirit, beyond the usual doomsday forecasts, even though he uses ideas and assertions from that source where they fit his purpose.

The major symptom of the crisis is, according to Camilleri, widespread alienation: "... political apathy, social anomie and mental or emotional dis-

order are the product of the dual process of domination and alienation to which the technological society subjects the human psyche" (p13). Drawing on a wide range of literature, including the various social sciences, philosophy, cultural critiques and analyses of current economic, political and military events on a world-wide basis, he suggests that only a radical change in international and national institutions can avoid disaster.

In discussing the economic and political dilemmas of the world and their manifestations in increased inequality, underdevelopment and instability technology emerges as the major villain, leading to bureaucratic centralisation in capitalist and advanced communist societies, testing existing institutions beyond their limits and creating an intolerable imbalance. But on p222 Camilleri pulls himself and the reader sharply up in recognising that he is in danger of throwing the baby out with the bathwater: "... we may have created the erroneous impression that technology lies at the root of the modern human predicament. The problem of domination and dehumanisation that we have been describing cannot be attributed to technology as such, but only to the specific role assigned to it by the ideology of industrialisation." But he remains evasive on

how international inequalities can be reduced without some ideology of industrialisation in poor countries. There are various hints in the book suggesting that the Chinese experiment in social organisation may be one way out of the dilemma. But Camilleri is too concerned with the liberation of the individual to suggest a wholesale transfer of an experiment whose authoritarian character the Western world is beginning to realise as the perhaps inevitable counterpart of its remarkable virtues and achievements.

Camilleri's "utopian vision" is culled from a number of thinkers of most diverse outlook—Marcuse and Pope Paul VI, Marx and Teilhard de Chardin, Mao and Gestalt therapists, Illitch and (surprisingly and only in a note) Skinner. The author is right, of course, in saying that any critique of the present involves at least logically a concept of what could be, and equally right in not proposing a blueprint but rather a set of human values which should be maximised in a new cultural synthesis. Central to this deliberately vague utopia is the small organic community where "the liberation of human sensitivity and sensibility is made a primary goal of social interaction" (p187).

It is to the author's credit that he does not shirk the question of how to make this often dreamt dream come true, even if his answer is more appealing for its sincerity and morality than convincing as a solution. Camilleri advocates a non-violent cultural revolution which he sees already emerging in the rich world: "Once the counter-institutions, whether it be free universities, underground churches, free presses, community schools, worker-directed enterprises or neighbourhood-controlled welfare services, have demonstrated their efficiency and legitimacy through a continuous process of innovation and experimentation based on service and direct participation, the established institutions are likely to collapse with little or no coercion required..." (p254).

One can hardly blame the author for not having solved all the world's problems. Nobody else has done so either. But such naiveté, together with many unexamined assertions and some inconsistencies in the book, overshadow its positive features.

The value of the book to a reader wishing to appraise the evidence on which the author bases his arguments would have been enhanced, had the index included references to the Notes.

Marie Jahoda, Professor Emeritus of Social Psychology, is now senior research consultant to the forecasting programme of the Science Policy Research Unit at the University of Sussex, UK.

## Hard and soft paths

P. F. Chapman

*Soft Energy Paths: Towards a Durable Peace.* By Amory B. Lovins. Pp. 254. (Ballinger: New York; Wiley: Chichester, UK, 1977.) Hardback \$15.40; £9 Pp. xx+231. (Penguin Books: Harmondsworth, UK, 1977.) Paperback 95 pence.

An energy policy involves a projection of energy demand at some future date coupled to a means of supplying the requisite quantities of energy in appropriate forms. Although there are radically different policies advocated, each with its own mix of supply technologies and demand estimates, virtually all policy analysts are agreed on the ground rules that must be used to evaluate or judge a policy. The first rule is that the demand projection and methods of energy supply should neither require nor impose any substantive change in consumers' lifestyle. The second is that all the technologies involved, either in supply or utilisation, should either be proven or have a demonstrably high chance of feasibility. The third rule is that the policy should provide energy at least cost. If this latter cannot be demonstrated then it is essential to demonstrate that all investments show an adequate return on capital. The differences between advocates of different policies can, under these agreed rules, be boiled down to different choices of important parameters, with each author accusing others of making choices of convenience. Since many of the important parameters are in principle unknowable, this leaves plenty of room for endless, and fruitless, debate.

In his new book, *Soft Energy Paths*, Amory Lovins attempts to use the agreed rule book to show that the "hard technologies" advocated by the establishment are significantly less desirable than the "soft technologies" proposed by environmentalists, conservationists, lovers of peace, and... Amory Lovins. The basic thesis of the book was published by Lovins in *Foreign Affairs*, an influential US quarterly. The article is reproduced as chapter 2 of the book, the remaining chapters serving to embellish and document the arguments. Although the approach and data in the book are clearly aimed at influencing US energy policy, Lovins makes it clear that the same principles and analyses could, and should, be applied in all industrial nations.

The 'hard' path described in the book is based on the policies of a number of US agencies, including the Energy Research and Development Agency. This policy has energy demand (in primary energy terms) doubling by the end of the century and increasing by as much again by 2025. Over the 50-yr period, oil and gas decline from a 75% market share to about 10% with coal and nuclear power accounting for both the growth and the substitution. Lovins argues against this policy in terms of changes in lifestyle and unacceptably high costs. He shows that the massive use of technical resources, the potentially enormous environmental damage and the security measures required for a massive nuclear programme, will alter the way of life of most Americans. He also argues, with considerable conviction, that the development of nuclear power will lead to the widespread proliferation of nuclear weapons with potentially enormous effects on 'lifestyles'.

Lovins' critique of the hard path on cost grounds is similar to many previous analyses. There is no doubt that the costs of nuclear systems are becoming embarrassingly large, and there seems to be no decrease in their escalation at a rate substantially faster than the rate of inflation. To this embarrassingly high cost, Lovins adds the equally enormous costs of distributing electricity to consumers. He then makes the numbers absurdly high by dividing by an unrealistically low 'load-factor'. This is silly, since it provides ammunition for those who would knock down an otherwise sound and important argument.

Underneath the critique of the hard path, there are a number of principles which show Lovins' previous training in physics. The first is an obvious distaste for waste of a physical commodity which, by any route, is going to be more expensive in the future. The second is the mismatch implied between the high quality of energy supplied to consumers (electricity) and their low quality energy requirements (low temperature heat). Lovins attacks the question of mismatch, directly as a matter of principle, without drawing on the obvious economic argument that rising prices will push consumers towards more appropriate fuels. This is perhaps because Lovins subscribes to Galbraith's thesis which puts sovereignty in the hands of producers not consumers.

Improving the match between energy supply and end-use function is one of the major starting points for the 'soft' path synthesis. Another is that if one can use ambient energy sources, particularly wind and solar, then one

# NEW FROM BUTTERWORTHS

## Remote Sensing of the Terrestrial Environment

Edited by R.F. Peel, L.F. Curtis and E.C. Barrett

An up-to-date review by leading experts of some of the ways in which the techniques of remote sensing, developed mainly for space research, could be used to increase our knowledge of the Earth itself and to achieve a better evaluation of its resources.

1977 286 pages £12.00

## Solar Electricity: an economic approach to solar energy

W. Palz

In this book, written by a scientific specialist, the reader will find a sound introduction to the science and techniques of solar energy. Specialists and prospective users of solar devices will also be interested by the reviews of the latest research and development work, the cost projections and the technical guidelines for working systems.

1977 320 pages £16.00 approx.

## Solid-Liquid Separation

Edited by L. Svarovsky

This latest book in Butterworths Chemical Engineering Series analyses and reviews recent important developments in this rapidly expanding field, bringing the reader up-to-date with the principles and practices of solid-liquid separation technology.

1977 346 pages £21.00

## Quantum Pharmacology

W.G. Richards

This important work breaks new ground in the application of the methods of physics to biological problems. The author believes that the methods of molecular quantum mechanics may be applied to good effect to the complex problems of molecular pharmacology.

1977 228 pages £12.00

## Antibiotics and Antibiosis in Agriculture

Edited by M. Woodbine

This volume reviews both the current state of research and progress in antibiotics and antibiosis within the ambit of agriculture and agricultural science. Synergism and synergic aspects are a linking theme. It will be of value to workers in food science, microbiology, animal nutrition and also those involved in veterinary science and the pharmaceutical industry.

1977 380 pages £18.00

## Plant Proteins

Edited by G. Norton

This collection of papers provides a comprehensive and up-to-date coverage of the production and use of plant proteins as sources of human food. It will be essential reading for workers in research and industry in the agriculture and food science fields as well as to plant physiologists and biochemists.

1977 346 pages £16.00

## Recent Advances in Animal Nutrition — 1977

Edited by W. Haresign and D. Lewis

This book contains contributions by leading international experts, describing in detail the various aspects of rumen fermentation. It will be valuable to students and research workers in animal nutrition as well as to the veterinary scientist.

1977 224 pages £11.00

## Control of Ovulation

Edited by D.B. Crighton, G.R. Foxcroft, N.B. Haynes and G.E. Lamming

This book reviews the current knowledge of the basic physiological mechanisms that contribute to the control of the female reproductive system with particular reference to the control of ovulation.

1978 380 pages £18.00 approx.

BUTTERWORTH & Co. (Publishers) Ltd  
Borough Green, Sevenoaks, Kent.

## Chemical Engineering Volume 4 Solutions to the Problems in Chemical Engineering, Volume 1 in SI Units

J.M. COULSON, *University of Newcastle upon Tyne*,  
J.F. RICHARDSON, *University College Swansea*,  
J.R. BACKHURST and J.H. HARKER, *University of Newcastle upon Tyne*.

Solutions to the 200 problems in the Third Edition of the first volume in the well-established and highly regarded 'Coulson and Richardson' series. The working throughout is in SI units. The series was greeted as:

"outstanding in this field . . . presenting a formidable challenge to all previous chemical engineering textbooks"

ISBN 0 08 020926 2	\$15.50	£8.75	Nature
ISBN 0 08 020918 1 flexi	\$ 9.50	£4.95

## The History of Man-Powered Flight

D.A. REAY, *International Research & Development Co. Ltd., Newcastle-upon-Tyne, England*

This book covers the history of man-powered flight, from early mythology to present-day sophisticated aircraft. As well as presenting data on the machines, the author has supplied background information on the philosophy behind the designs, the controversy surrounding some areas of development, and the role played by serious contemporary aeronautical institutions. Special features include a unique detailed account of the personalities involved as well as the aircraft themselves, the background to many of the man-powered flight competitions, the successes and failures worldwide. Also included is the work of Ursinus in Germany in the 1930s, a particularly detailed account of the growth of activity in the UK between 1955 and 1965, and data on aircraft due to fly for the first time during 1977.

ISBN 0 08 021738 9	\$15.00	£7.50
362pp	175 illus	November 1977

## Electrical Power Systems, Volumes 1 & 2, (2nd Edition in SI/Metric Units)

A.E. GUILLE, *University of Leeds, England* and  
W. PATERSON, *Leeds Polytechnic, England*

This two-volume textbook provides a comprehensive and up-to-date account of the subject of Electrical Power Systems and their applications. Each volume is largely self-contained and collectively they form a unified course covering the important aspects of the subject, with special chapters on circuit interruption and switching over-voltages; high voltage DC systems; 3-phase network matrices and co-ordination system transformations; the use of matrix methods for the solution of power system problems by digital computer.

A selection of useful worked examples and problems with answers (over 300) are included and points for further development are also suggested to assist lecturers set work for students themselves to study. August 1977

## Biochemistry of Characterized Neurons

Editor: N. OSBORNE, *Max-Planck Institut für Experimentelle Medizin, Göttingen*

This book is aimed at the neurobiologist and is designed as an up-to-date report on the biology of characterized neurons in the central nervous system. Its major emphasis is on the biochemical, morphological and functional aspects of characterized neurons and the techniques used in these studies, but importance is also given to the ways of isolating neurons. The book will consist of ten main chapters and one introductory chapter, each written by a currently active research worker and an expert in his field

ISBN 0 08 021503 3	\$30.00	£16.50
250pp		1977

## Towards a Plan of Actions for Mankind

Edited by M. MAROIS, *Institut de la Vie, Paris*, in five volumes

Towards a Plan of Actions for Mankind was a World Conference held in Paris and sponsored by Valéry Giscard d'Estaing. The complete proceedings and the main discussions are published in five volumes: 1977

Volume 1 — Long Range Mineral Resources and Growth which discusses the problems of mineral source availability and depletion.

ISBN 0 08 021445 2	50 illus	\$60.00	£33.00
328pp			

Volume 2 — Long Range Energetic Resources and Growth which relates energy and its resources to our current and future social, economic and technological systems.

ISBN 0 08 021446 0	\$40.00	£22.00
182pp	38 illus	

Volume 3 — Biological Balance and Thermal Modifications which discusses in detail the effects of thermal pollution on the environment.

ISBN 0 08 021447 9	115 illus	\$60.00	£33.00
318pp			

Volume 4 — Design of Global Systems and Their Limitations which deals with the design and application of models for planning, decision-making and control.

ISBN 0 08 021448 7	\$55.00	£30.50
258pp	59 illus	

Volume 5 — Conclusions and Perspectives which provides a complete summing-up of the entire conference with transcripts of some of the most interesting and fruitful discussions.

ISBN 0 08 021449 5	\$100.00	£55.00
206pp		

5 Vol. Set ISBN 0218504

The complete set may be purchased at \$267.00 £148.50 (a discount of 15%) but each individual volume offers a complete record of the papers presented in the subject areas indicated, and may be purchased separately.

## Chemicals for Crop Protection and Pest Control

M.B. GREEN, *Hartford, Cheshire*, G.S. HARTLEY, *Hamilton, New Zealand* and T.F. WEST, *Tylers Causeway, Hertford*

This completely revised version of CHEMICALS FOR PEST CONTROL is an up-to-date consideration of pesticides as articles of manufacture and trade by the chemical industry, relating their use, hazards, regulatory control and biological activities to this. Discusses the technological economics of crop protection and pest control, predicts future trends and visualizes the integration of pesticides into total systems of pest management.

can avoid most of the costs of energy transmission. To these significant advantages, Lovins then adds a number of very dubious cost advantages associated with small scale mass production (as opposed to large scale one-offs). It is here that Lovins falls into the ubiquitous trap of choosing data that happily proves his case. Two examples illustrate the type of problems involved.

First, Lovins suggests that car engines provide a system of electricity generation at a cost of \$40 per kW compared with power station costs of more than \$400 per kW. Lovins omits, however, to cost the 100 kW generator that needs to be coupled to the car engine. More seriously, his argument for mass production is undermined when it is realised that a car engine is worn out after 4,000 h of running time, whereas a large generator is expected to run for 6,000 h per yr for 20 yr or more.

The second example concerns the cost of solar energy systems. Lovins is only concerned with the cost of active solar systems, employing flat plate collectors and large hot-water heat stores. He arrives at a figure of \$100/m<sup>2</sup> of collector *plus* a m<sup>3</sup> of storage. In the UK, an optimistic cost for solar collectors is £50/m<sup>2</sup>. The cost of storage in the UK has been put at £300/m<sup>3</sup> by the Buildings Research Establishment. By using cheap agricultural tanks and the cheapest methods of installation and insulation this cost can be reduced to £40/m<sup>3</sup> for moderate tank sizes (over 40 m<sup>3</sup>). Thus UK costs are at best £90 per (m<sup>2</sup>+m<sup>3</sup>), equivalent to £150. This estimate is, however, still too low, since it ignores the cost of loss of house space and control equipment. The 50% difference between the most optimistic UK figure and Lovins' data is sufficient to cast serious doubts on the cost-effectiveness of active solar systems.

There are other serious criticism of the proposed 'soft path'. Throughout the book Lovins fails to produce comprehensive data on how much energy is to be supplied by what source for use by which consumers. Many attractive back-of-the-envelope calculations fall down when examined in detail, especially in complex energy systems. There is also no adequate discussion of the environmental effects of the soft path. In this respect, windmills are clearly cast in doubt, and outside the US there are few countries who could afford much acreage for growing 'biomass' fuels.

Although Lovins' book does fail on a number of technical issues, this is more than compensated by his breadth of approach. Energy policy questions are cast in a very general sociopolitical framework and a number of important questions raised. Of these, the relation-

ship between nuclear power, centralised control and weapons proliferation are the most important and urgent. Is any energy policy important enough to threaten every nation's foreign policy?

Although Lovins clearly identifies many of the central issues, one is left with a number of important questions unanswered. The last four years have seen some remarkable shifts in attitudes towards the alternative (or soft) energy technologies with most nations now actively supporting a very diverse energy research and development programme. There remains, however, an enormous commitment to nuclear power. The costs are embarrassing both the utilities in the US and the Central Electricity Generating Board (CEGB) in the UK. (Here, it is interesting to note that the CEGB is supporting British Nuclear Fuels Limited at Windscale, despite their admission that reprocessing will cost them about £300 million more than obtaining fuel from uranium ore).

## Energy forecasting

Walt Patterson

*Energy or Extinction? The Case for Nuclear Energy.* By Fred Hoyle. Pp. vii+81. (Heinemann Educational: London, 1977.) Paperback £1.50.

COSMOLOGY does not, on the face of it, have much to do with the subtleties of terrestrial economics and politics. Nevertheless, Sir Fred Hoyle has taken a flying leap out of the galactic depths and into the middle of one of today's most immediate and heated controversies. Sir Fred, of course, is no stranger to controversy. He is, however, something of a stranger to energy policy, as he demonstrates repeatedly in his lively polemic *Energy or Extinction?* He writes, as usual, with flair and enthusiasm. All too often, however, he finds himself out of his depth.

The tone is set by Sir Alan Cottrell's Foreword to the book: "It is about energy: about the alarming prospect that oil will soon run out and not be replaced by anything else. It shows that—contrary to an influential belief—we do *not* have time, that there is *no* practical alternative to nuclear energy . . ." After this outburst, Sir Alan goes on to deplore the "hysteria of the anti-nuclear environmentalists". Both the Foreword and the book it introduces bear witness that environmentalists have no monopoly on hysteria. Sir Alan's allusion to the book's "refreshing commonsense" runs afoul of its

Wherein lies the source of this commitment? Is it the massive investment in nuclear technology? Is it the enormous institutions built-up on nuclear technology employing so many highly qualified scientists and technologists? Or is it perhaps the military link? Lovins book is causing ripples in the US and may encourage President Carter to go further with his non-proliferation policies. It will certainly provoke interest and controversy in the UK. But before any action can be taken on a 'Soft Energy Path; Toward a Durable Peace', someone will need to analyse the soft path in far greater detail and be able to account for the commitment to the hard path policies presently being followed by all the industrial nations of the world. □

*P. F. Chapman is Senior Lecturer in Physics and Director of the Energy Research Group at the Open University, Milton Keynes, UK.*

very title; do we really have to choose now between "energy or extinction?" It is an emotional catchphrase that begs almost all the important questions.

Sir Fred's approach to energy policy is based on a series of non-negotiable assertions couched in stark all-or-nothing terms: "There can be no disagreement with the statement that world reserves of coal, oil and gas can provide an adequate energy source for only a limited future . . . nor can it be contested that most of the world's population . . . will die in a disastrous catastrophe should an adequate energy source not have been developed by the time that reserves of coal, oil and gas become exhausted . . . nor can there be any serious debate over the statement that the only alternative energy source *presently known to be technically viable* (italics in original) is energy from the nuclear fission of uranium or thorium". If Sir Fred genuinely believes that none of these assertions can be disputed, he has somehow failed to notice the boiling ferment now engulfing energy policy worldwide.

He has also overlooked a fundamental consideration which is likewise absent at key places elsewhere in the book: the matter of cost. Even "reserves" of fuel depend critically on the extraction cost assumed, as well as the value assigned to the fuel in use. "Most of the world's population", however, presently depends largely on forms of energy which are not bought and sold. Technical "viability"—surely a contradiction in terms—is long since proven for many energy technologies, and is not the central problem. The primary problems are economic—how much money and time we are prepared to

spend on various aspects, especially investment; social—the costs and benefits, and how they are to be apportioned, especially employment; and political—who shall decide, and how. Despite Sir Fred's suspicions, the factor now impeding nuclear development is not the third but the first of these: the cost and the lead-time.

Sir Fred belongs to the traditional school of energy forecasters, whose motto is "Think of a number and double it". He notes that Britain's per capita annual use of energy is only about half that of the US: "this of course is the over-riding reason why the standard of living is lower in Britain than it is in America. By doubling the British energy flow, our standard of living would rise inevitably towards the American level". That being so, why do we not simply turn up the central heating and open all the windows? The putative link between GNP and energy use looks more tenuous every year, to say nothing of that between GNP and 'standard of living' in meaningful terms. Sir Fred, however, desires "to raise the standard of living of everybody in the world to the American level"—presumably by American cultural standards, universally acknowledged as the acme of human accomplishment. It seems not to trouble him that the immediate requirement of most of the planet's people is for local energy systems, using local skills and most of the planet's people is for local money. In most Third World countries, capital-intensive centralised electricity systems are a comprehensively inappropriate misallocation of effort, as even the World Bank is coming to accept.

Sir Fred is convinced, however, that this is how we must deploy our resources. He is concerned with energy supplies 30,000 years hence, but has a shakier grasp of more relevant time-scales. "It is a mistake to think that conservation could go very far towards mitigating our future need for energy. Conservation could moderate the need, but by no great margin, for *if the margin were great, conservation would have happened already*". Our present pointlessly wasteful infrastructure—buildings, transport, industrial plant—was established during a period of absurdly cheap energy. This infrastructure cannot be replaced overnight with one more appropriate to a time of high energy price. Such replacement, however, is already underway; and it does not in any way imply—in Sir Fred's phrase—a "hairshirt economy" (see, for instance, the evidence given by Friends of the Earth to the Windscale inquiry).

Sir Fred's lack of first-hand acquaintance with the work and views of Friends of the Earth led him and his

publisher into a slight contretemps. The opening chapter of the book suggests in lurid terms that critics of nuclear power like Friends of the Earth are agents or dupes of the Kremlin. Before the book's publication, however, Sir Fred and Heinemann added and circulated a statement, withdrawing all imputations of 'reds under the reactors'; and two staff members of Friends of the Earth were guests at the book's publication party.

There are a few lapses which Sir Fred should have caught: "molecules" of salt? His discussion of the nuclear option itself suggests that he needs further homework here as well: "fuel elements" or "fuel assemblies", but not "fuel cells", and power reactor control rods are not made of cadmium. His discourse on radioactive waste commences with another brisk wave of the hand: "I have always been asked about the 'problem' of the disposal of radioactive wastes. There is no problem, and the thought that there is, if the concern is genuine, can only come from ignorance and from a fear of the unknown". Perhaps he should have a word with Sir Brian Flowers, whose ignorance and fear of the unknown are conspicuous by their absence. Sir Fred's otherwise generally lucid prose ties

itself in knots during his attempts to banish the non-problem. He also gets the half-lives of both strontium 90 and caesium 137 wrong.

Much the most unsatisfactory paragraph in the book, however, is his extraordinary dismissal of the issue of nuclear weapons proliferation. Rarely have I seen such wilful sophistry as the assertion that linking nuclear energy and nuclear bombs is on a par with linking "eating a piece of chocolate and exploding a hand grenade" because "both (are) manifestations of chemical energy". This will not do, and Sir Fred should know better.

It is ironic that—assuming we move quickly to resolve the nuclear weapons problem—the so-called "anti-nuclear environmentalists" are today the optimists, who foresee an abundance of options and are working eagerly to respond to the challenge. Those who insist that the choice for humanity now lies between nuclear energy and freezing in the dark are—in Sir Fred's verbal boomeranging—"scaremongers whose prime concern is to frighten people". Cheer up, Sir Fred—from where we sit the view is really rather encouraging. □

Walt Patterson is Energy Consultant to Friends of the Earth (London) Ltd.

## Epic work on climate

John Gribbin

*Climate: Present, Past and Future*. Vol. 2: Climatic History and the Future. By H. H. Lamb. Pp. 835. (Methuen: London; Barnes and Noble: New York, 1977.) £38; \$85.

THE arrival of the second volume of Professor Lamb's epic on climate has been eagerly awaited by everyone working on studies of the climate. The first duty of any reviewer is to report that the book is no disappointment, fulfilling the high expectations of those who have already found the first volume indispensable. That said, it might seem that further comment is superfluous; but since 1972, when volume 1 of *Climate: Present, Past and Future* appeared, debate about climatic change has moved so much into the realms of the planners, politicians and concerned laymen with no specialist training in the subject, that the book is now of far wider significance, and likely to have a much broader impact, than even the author could have imagined when he began his mammoth task twelve years ago.

Recent vagaries of the Earth's atmospheric system have been front-page news around the world, and include record-breaking drought followed by record-breaking precipitation in England; simultaneous severe drought in the western US and heavy snowfall in the east; failures of the monsoon in some parts of the world; and frosts in Brazil, which have been used as an explanation of recent dramatic increases in the price of coffee. The latest annual report of the UK Meteorological Office was the subject of a first leader in *The Times* in which the writer commented "there seems little doubt that the world's climate has been changing", and was taken to task by a member of the School of Geography in Oxford who argued that it has all happened before and refused to accept "that recent weather events in Britain provide reliable evidence for a significant climatic change".

When the world's weather seems to be turned topsy-turvy, but specialists can be found prepared to argue any of the cases that: (1) nothing unusual is happening; (2) we are hastening towards a new Ice Age; or (3) present troubles are caused by the greenhouse effect of human activities which produce carbon dioxide and warm the globe, the wretched non-specialist—

## Contents:

Materialism Transcends Itself. The Worlds 1,2 and 3. Materialism Criticized. Some Remarks on the Self. Historical Comments on the Mind-Body Problem. Summary.—The Cerebral Cortex. Conscious Perception. Voluntary Movement. The Language Centres of the Human Brain. Global Lesions of the Human Cerebrum. Circumscribed Cerebral Lesions.—The Self-Conscious Mind and the Brain. Conscious Memory: The Cerebral Processes Concerned in Storage and Retrieval.—Dialogues.

This book is timely, as it appears at a point of impasse between philosophy and science. It creates the first link between the philosophy of the self and neurobiology. In dealing with the self, philosophers have so far taken little account of scientific knowledge of the brain; scientists, for their part, have traditionally avoided philosophy in favour of purely material evidence.

Eccles (a neurobiologist) and Popper (a philosopher), both believers in dualism and interactionism, consider the existence of consciousness one of the greatest riddles of cosmology.

In Part I, Popper discusses the philosophical issue between dualist or even pluralist interactionism on the one side, and materialism and parallelism on the other. There is also a historical review of these issues.

In Part II, Eccles examines the mind from the neurological standpoint: the structure of the brain and its functional performance under normal as well as abnormal circumstances, for example when lesions (especially those surgically induced) are present. The result is a radical and intriguing hypothesis on the interaction between mental events and detailed neurological occurrences in the cerebral cortex.

Part III, based on twelve recorded conversations, reflects the exciting exchange between the authors as they attempt to come to terms with their conflicting opinions. This part preserves the intimate quality of these dialogues, and shows how some of the authors' viewpoints changed in the course of these daily discussions.

Circle No. 22 on Reader Enquiry Card.

who, in this case, may be involved in attempts to improve agricultural productivity to meet the needs of a growing global population—needs some secure foundation on which to base his interpretation of climatic events. Professor Lamb's books provide that secure foundation, and the second volume is of particular importance to anyone concerned in an empirical way with changes in climate, concentrating as it does on climatic history and on implications for the future.

The simplest and most reliable guide to the climate is that if something has happened before it can happen again. Professor Lamb's look at what has happened before covers successively, and in increasing detail, the long history of the Earth, the Quaternary, postglacial times, the historical record, and the period of instrumental records. This natural division of attention reflects, of course, the amount of detailed information available, but also concentrates on the periods of most interest now—the most recent fluctuations in climate. With an outline of more distant, long term events as background, the changes since the most recent full glaciation provide the appropriate insight into what may be happening to climate today. Suggestions that man's activities are solely responsible for increased Saharan desertification, for example, should be considered in the light of evidence about past development of the desert; this would seem to indicate that both the Sahara and Kalahari deserts spread towards the equator during periods of cooling climate.

Cooling phases are likely to be of particular interest at the present time, since the consensus of various forecasts assembled by Professor Lamb is that we are likely to see a continued global cooling over the next 30 years or so. This is not to say that we yet have reliable means to forecast such changes in detail, but "encourages belief in the possibility of developing a real forecasting skill in relation to such periods ahead, and suggests that some useful guidance has already been obtained from this scientific research". The joker in the pack, however, is the prospect that mankind's activities, most likely the carbon dioxide greenhouse effect, will introduce a significant new variable into the climatic system just at a time when we are on the brink of understanding the natural processes.

Professor Lamb's great achievement is that he has assembled in one place a vast store of information about the climate, encapsulating present knowledge at this critical watershed in the development of such an understanding. As a sourcebook for everyone working on the subject, the book would be

invaluable even if it were not well written; in fact, the author presents his material (from the implications of plate tectonic theory to the effects of mankind's activities on climate) so clearly that the volume would be a pleasure even to the casual reader who might dip into the sections on historical changes in climate and effects on human activities. Alas, I use the word "might" advisedly; for the price of the present volume is so great as to preclude any casual reader, along with many who have a serious interest in the subject.

At £38 (in the UK) for a single volume—even one of major importance, well written and more than 800 pages long—the publishers must surely be reaching the point of diminishing returns. Can any working scientist possibly buy such a book? And, indeed, can all of the libraries that might wish to have it on their shelves justify the cost? It must also be mentioned, in view of the large capital investment such a book represents, that although the volume's presentation and layout is, overall, of a high standard many of the figures have not been re-drawn into a standard format, but are simply reproduced from their original sources. Although all are acceptably clear and no harm is done to the intelligibility of the book (except where the labelling of the figures is retained in its original Norwegian), this is hardly the kind of penny-pinching usually associated with such an investment. The presentation and cost of the two volumes may have seemed appropriate when the project was initiated, but in view of the much more widespread interest in the topic now it would be good to see the whole

work available in more accessible format—perhaps as a series of three or four paperbacks which might be purchased individually as finances permitted.

But for anyone fortunate enough to possess the book and its companion volume the intrinsic value is unquestionable. It is impossible to do justice to Professor Lamb's achievement in the short space available here, and it will take months to begin to absorb the impact of this appraisal of the background to present-day climatic problems—followed, I am sure, by a lifetime in which it will remain a much used and valued reference. Perhaps the final words should be left to the author. First, a statement of intent from the Introduction which aptly describes the work: "This book is an attempt to marshal existing knowledge of climate and its behaviour, so as to provide a basis on which forecasting techniques will have to be developed".

And, finally, from a footnote (the many comprehensive footnotes are themselves one of the major delights of the book) commenting on those historians who do not accept that climatic change was contributory to the cultural decline and other disturbances of the Middle Ages in Europe, a remark which is strikingly apposite in view of the current climatic debate: "There is great need for open minds and a careful integration of knowledge". □

## Encyclopaedic jungle

Peter J. Smith

*Planet Earth: An Encyclopaedia of Geology.* Edited by Anthony Hallam. Pp. 319. (Elsevier/Phaidon: Oxford, 1977.) £7.95.

THE publishing world seems to have gone mad as far as the production of geological dictionaries, encyclopaedias and the like is concerned. I reviewed three such volumes earlier this year (*Nature*, 266, 101; 1977); several were then already in existence; another appeared a month or so ago; I have a new one to review here; and the publication of at least two more is imminent. This field, once so barren, is rapidly developing into a jungle; so this seems a good time to hack a way

through the undergrowth before it rises even higher.

Of course, not all works of the genre under consideration here are aimed at the same audience and not all cover precisely the same ground in precisely the same way. The massive *Glossary of Geology* (American Geological Institute: Washington DC, 1972) covers the whole range of the Earth sciences with some 33,000 entries which are generally short and highly technical. This is the working Earth scientist's bible and is likely to remain so, at least until the Institute summons up the courage to produce a new (third) edition. Not to be dismissed lightly, however, is the more humble *Penguin Dictionary of Geology* (D. G. A. Whitten and J. R. V. Brooks; Penguin: Harmondsworth, UK, 1972) which contains far fewer terms than the *Glossary* but devotes rather more words to each. Its language is perhaps best described as semi-technical, which makes the book useful to specialists

and comprehensible to students but hardly the sort of work the general reader would care to browse through.

The most serious objection to the Penguin dictionary is its weakness on geophysics, a gap that is filled to some extent by *A Dictionary of Earth Sciences* (S. E. Stiegeler; Macmillan: London and Basingstoke, 1976). I say "to some extent" because although the gap is undoubtedly filled, the relative shortness of the entries in the Stiegeler volume is not very helpful to those with no previous knowledge of the subject. This is a trap generally avoided by *Earth Resources: A Dictionary of Terms and Concepts* (D. Dinley et al.; Arrow: London, 1976) with its longer, more informative entries, although, as its title suggests, this book is narrower in scope.

If a distinction is to be made between dictionaries and encyclopaedias, all the books mentioned above, whatever their intended audience, would best be described as dictionaries; their entries, though generally not single-sentence definitions, are short and arranged alphabetically; and illustration, if any, is limited to a few line diagrams. By contrast, *The Planet We Live On: Illustrated Encyclopedia of the Earth Sciences* (C. S. Hurlbut; Abrams: New York; New English Library: London, 1976) comes closer to the popular idea of an encyclopaedia in that it contains hundreds of diagrams and photographs as well as numerous colour plates. Unfortunately, as I have had cause to remark before, this book contains so many inaccuracies that the whole stock is best left to rot in the publisher's warehouse. The point of mentioning it again here, however, is, first, to reiterate that warning and, second, to report that it is now possible to recommend to the general reader a book which, though similar in aim, is far superior in execution.

At the risk of being accused of using unscientific terminology, I can only describe *Planet Earth: An Encyclopedia of Geology*, edited by A. Hallam, as beautiful. It is nice to look at; colour photographs and/or diagrams adorn almost every page without making for simply a picture book with incidental text. It is accurate and authoritative; almost all the writers have been chosen from the ranks of those still active in the subject "because an understanding of the Earth depends on an appreciation of the fruits of recent research". It is for the most part well written—no mean achievement given the literary standards of a great many research workers. And it has a remarkably wide coverage, including some topics, such as engineering geology and the history of geology, which are all too often ignored.

It is also unconventional, in that it is arranged not alphabetically but in nine major sections each of which is subdivided into a series of closely related subjects. Thus, to take but one example, the section, "Processes That Shape the Earth", includes discussion of continental drift, weathering, earthquakes, diagenesis, and so on. The effect of this arrangement is to give the book a remarkable coherence. The pleasure of reading a text broken up into a series of 'terms' related only by the chance occurrence of their initial letters is strictly limited in my view, however useful such a book may be for reference. The delight of Hallam's approach is that it has produced not only a good work of reference (for the book has an excellent index) but also a more or less continuous text which cleverly directs the eye towards horizons beyond that originally sought. In short, it encourages the sort of pleasurable self-education that the disjointedness of an alphabetical arrangement can hardly begin to provide.

## Provocative but not profound

David Davies

*Ten Faces of the Universe*. By Fred Hoyle. Pp. 224. (Heinemann Educational: London, 1977.) £4.80.

THIS is the fourth book, to my knowledge, out of Cockley Moor this year and its publishers call it "perhaps Fred Hoyle's most provocative and profound book yet". Provocative it certainly is in parts—small parts—but profound it is not, and the lack of profundity only serves to devalue the provocation to something rather trivial.

The ten views of the universe are respectively God's, the physicist's, the mathematician's, the astrophysicist's, the expanding, the origin of the, nobody's (quantum mechanics), the geophysicist's, the biologist's and Everyman's. Hoyle has devoted an average of twelve pages of text to each; the rest of the book is made up of ten pages of chapter headings, ten more of pictures of people central to each chapter (with the relevance frequently left to the reader to work out); forty-seven pages of illustrations, many of them barely relevant; eight pages of star maps and coordinates; three pages listing details of all the elements; and four pages completely empty. The intended audience is American, to judge from the spelling and the baseball analogues,

So Hallam has nothing to fear from Hurlbut. He does, however, have more serious competition in the form of *The Physical Earth* (Mitchell Beazley: London, £12.50), one of the volumes in the much publicised Mitchell Beazley *Joy of Knowledge Library*. Despite the title, about one-half of this book is devoted to plants, animals and agriculture, although to the general reader the Earth science section will appear as attractive as *Planet Earth*, and for similar reasons. If forced to choose between the two books, I would go for Hallam, partly because the space devoted to the Earth sciences proper is greater and partly because the rather higher proportion of text to illustration somehow imparts to Hallam's work less of a coffee-table feeling. Besides, there is a considerable price differential. In comparison with books of similar format and physical quality the cost of *Planet Earth* is remarkably low.

Peter J. Smith is Reader in Earth Sciences at the Open University, Milton Keynes, UK.

and presumably at the intelligent layman level.

The book starts on a poor note. Hoyle gives the impression he will discuss the place of a God in or outside the Universe. But he soon gets distracted into rambling anecdotes about his solution for Northern Ireland, how children learn mathematics, what his schooldays were like, and how Galois met his death. Thereafter the book is not free of its irritating diversions, but does follow a more orderly path. Hoyle certainly would not claim to be presenting other than thumbnail sketches of physics, mathematics and cosmology but there are some nice things therein, and insights that even a hardened scientist might find useful. The two chapters on geophysics and biology, not so close to Hoyle's lifelong interests, are accordingly more pedestrian.

Then we come to Everyman's Universe which is about energy, population and the collapse of society. Hoyle suggests that he could have devoted a whole book to these subjects. It is certain that a chapter tacked on the end is totally inadequate and fails to give much impression of deep and sustained thinking. Hoyle, like many others, is worried about population growth, but unlike most others he tries to discuss it in terms of simple-minded graphs and immensely accurate prediction. The world will collapse into a Dark Age in 2025, give or take a decade or two. How is this figure reached? We are not told. Why should productivity (whatever that means) and population collapse so dramatically? Because the Roman Empire did. Why should the

phenomenon "perhaps have a cycle time of about 500 years"? We are not told.

Hoyle the scientist has become Hoyle the crystal-ball gazer but retaining a pseudo-scientific veneer of graphs, cycles and so on. And his draconian proposal that we should stop all this growth by heavily taxing three-children

families just comes as a flashy bit of provocativeness which really advances serious thinking on problems in the real world very little.

In all, a strangely mixed book, at times charming, at times half-baked. □

David Davies is Editor of Nature.

## Cosmic gushers

Roman Znajek

*White Holes: The Beginning and End of Space.* By John Gribbin. Pp. 200. (Paladin: London, 1977.) £1.50; \$4.50.

A WHITE HOLE is like a black hole, but with time running backwards. Nothing can get out of a black hole, and nothing can get into a white hole. Whenever a black hole is formed, matter that is unable to withstand its own gravitational field collapses to form a point called a singularity. A white hole is *caused* by its singularity. The latter is best thought of as a remnant of the initial singularity from which the Universe began in the Big Bang. According to John Gribbin, if we are prepared to accept the existence of black holes then "the rest of the new astronomy inexorably follows", and that includes white holes. His book is intended to be a popular account of some of this new astronomy.

Now nobody knows for certain what a white hole singularity is going to do, and indeed nobody knows why it should be there at all. It is, however, not unreasonable to suppose that at some stage in its career it will start spewing things out and turn into a cosmic gusher, as Gribbins like to put it. Because the amount and nature of the gush is completely unknown, Gribbin has no difficulty in 'explaining' various highly energetic phenomena of extragalactic astronomy in terms of these cosmic gushers.

The conventional view is that quasars, radio-galaxies, and so on, derive their energy from matter in strong gravitational fields. For example, when gas spirals in towards a black hole very large quantities of heat are released through friction. There are reasons for expecting that kind of process to occur, even though there is much debate over the details. There are no reasons for expecting white holes to occur. Gribbin disagrees. According to him, the Big Bang is a white hole, and so there is every likelihood of there being others. But the universal Big Bang is a very different

phenomenon from the local white holes he thinks are responsible for quasars. What Gribbin cannot explain is why the Universe's initial singularity should have been deformed in such a way as to give rise to white holes.

Even if white holes did exist in the early Universe, they would have been very rapidly destroyed. In 1974, Douglas Eardley showed that white holes are unstable. A white hole attracts radiation and matter. But this material cannot get into it. It piles up on the surface of the hole, getting continuously accelerated. An exponentially strengthening 'blue sheet' is formed, which twists round the gravitational field and turns the white hole into a black hole. The black hole remains, because black holes are stable. The process is very rapid, and only ridiculously large white holes would survive into the present epoch.

It is interesting to see how Gribbin tackles this problem. First of all, he refers to Eardley's work as a "suggestion". He then says that "better physics is needed to deal with the situation". This is correct in so far as we don't know why the white hole is there, but given its existence Eardley's argument is immediately applicable. Gribbin finishes by claiming that this difficulty "is more than compensated for by the amazing discovery in the mid-1970s that black holes can explode". This is the cue for five pages on the Hawking process, which is interesting in itself but completely irrelevant to Gribbin's cosmic gushers.

The possession of unconventional ideas does not disqualify a person from writing a popular book. But he should at least give a good account of the orthodox view. Gribbin doesn't. The saddest thing about his book is that his astronomy is old. It is five years or so out of date. In the sixties astronomers were often baffled by the objects they saw through their telescopes, and were prepared to believe in all kinds of curious explanations. It now seems that there is no need to invoke unlikely objects such as white holes in order to understand quasars. White holes are old-fashioned. □

Roman Znajek is an SRC Postdoctoral Fellow at the Institute of Astronomy, Cambridge, UK.

# Amplifying by stimulated emission

Harold Weaver

*Celestial Masers.* By A. H. Cook. Pp. 135 (Cambridge University: New York, London and Cambridge, 1977.) £7.50.

ANY new technological development that makes possible astronomical observations in a previously unexplored spectral range never fails to have a strong impact on the science. Radio astronomy (which covers the spectral range from about one millimetre to longer wavelengths of many meters) provides many examples. The science itself was started accidentally by Karl Jansky in 1931 when he discovered radio radiation from the Galaxy. It has developed rapidly since the late 1940s, providing an extraordinarily rich harvest of new information and broadening enormously our view of the nature of the Universe. It first demonstrated the existence of synchrotron radiation, generated by relativistic electrons spiraling in magnetic fields in our own Galaxy and others.

Quasars, pulsars, and the all-pervading 3 K black-body radiation that is the relic of the original big bang that marked the start of the expanding Universe, are all discoveries of radio astronomy. The first spectral line in the radio range (the radiation arising from neutral hydrogen at a wavelength of 21 cm) was discovered in 1951, and the first molecular line in the radio range (originating in the hydroxyl radical OH) was observed in 1963.

Since then, radio astronomy has greatly changed astronomers' views of the chemistry of the interstellar medium. Radio astronomy has shown that polyatomic molecules, earlier thought to be highly improbable if not impossible in the interstellar medium, do, in fact, abound in the dark cool clouds of interstellar space. Radio spectral lines from several dozen different polyatomic molecules, some containing up to nine atoms, have been observed.

An extraordinary feature of the radio lines of the OH molecule was discovered in the course of a series of observations made at the Hat Creek Observatory of the University of California at Berkeley during 1964–65. The Hat Creek programme called for observations of all likely radio sources in which the OH molecule might appear. Many clouds containing OH were found, but in a few cases in which

dark clouds were associated with regions of ionised hydrogen excited by hot, ultraviolet emitting stars, the behaviour of the four spectral lines in the multiplet observed was totally anomalous.

The shapes and strengths of the four lines of the multiplet seemed to have little or no relationship to one another, a situation completely out of keeping with theoretical predictions. The lines were mixtures of broad absorption and numerous sharp emission components. Subsequently, it was found that in some instances the sharp emission features were polarised (some linearly, some circularly), and that some features varied in intensity on the timescale of a few weeks. The emission components originated in regions of the dark clouds having angular diameters far smaller than could be resolved by any single radio telescope. Later observations showed that the OH emission came from areas less than  $10^{-2}$  arcs in size.

It is an interesting historical sidelight that, while these observations were in progress at Hat Creek, similar observations were being made at the Harvard Radio Astronomy Observatory, where the same peculiarities were independently discovered. Neither group knew of the work of the other. By chance, the discovery was published first by the Berkeley investigators.

The peculiarities of the OH emission combined with the intensity of the radiation and the small signs of the sources from which it originated, were clearly inconsistent with spontaneous emission from a gas in thermal equilibrium. Amplification by stimulated emission must be taking place. Natural masers (microwave amplification by stimulated emission of radiation) in astronomical objects were thus accidentally discovered a few years after masers were invented on Earth. An interesting speculation will always remain as to how the theory of masers might have developed if the astronomical observations had come first.

In his brief 135-page monograph Professor A. H. Cook deals with the observation and interpretations of these intriguing astronomical objects. The topic has, of course, grown greatly in the 12 years since the first discovery. It is now known that not only does the OH group but also the H<sub>2</sub>O and other molecules, show maser action. Theories of "how it works" are numerous.

In the preface to his book Professor Cook states: "I have not presumed to write a book that will sum up the subject and give an explanation. Rather I have tried to bring out what is not known; no doubt I shall provoke disagreement, and if that disagreement leads to new knowledge and insight,

much of my purpose will have been achieved. This is meant to be an interim report and a stimulus for further study." Professor Cook has very successfully achieved his goal. His summaries and concluding remarks should prove stimulating to both seasoned workers in the field and to those who may wish to enter the field.

Of the six chapters in the book, Professor Cook devotes the first two to a short account of selected spectral lines in radio astronomy and a very brief review of those principles of molecular structure and spectroscopy required for discussion of celestial masers. He illustrates the topics covered with examples from OH and H<sub>2</sub>O sources.

The third and longest chapter provides a very adequate summary of observations of maser action for OH and H<sub>2</sub>O sources. Here, Professor Cook has steered a straight and true course, emphasising and summarising those features that are important for a basic understanding of the topic and foregoing the very large amount of detail found in extensive research papers.

In explaining the amplification of stimulated emission (chapter 4), the author adopts a phenomenological point of view and avoids a general quantum mechanical treatment. He provides clear brief derivations or explanations of the principal aspects of astrophysical masers, such as the equations of transfer and rate, the meaning of saturated and unsaturated masers, gain, linewidth, and the like. But the author's major thrust in this chapter is to point out the gaps in current knowledge. "We do not assuredly know", he writes, "how to account for the small angular sizes of sources, the isolated distribution of individual sources, the single sense of polarisation in hydroxyl, and, again in hydroxyl, radiation in only one transition. Possibly the greatest lack is the absence, so far, of any but the sketchiest account of lasers varying with time".

After reviewing quite thoroughly in chapter 5 the many schemes that have been suggested for pumping, that is, for inverting the populations in OH and H<sub>2</sub>O sources to produce a maser, Professor Cook goes on in chapter 6 to provide an analysis and interpretation of maser radiation. Here he attempts "to see how far the sources can be accounted for by amplification of stimulated emission and to use the analysis to set conditions that must be fulfilled by any pumping mechanism. Other clues to pumping mechanisms may be provided by the statistical properties and associations of maser sources". The chapter is a very interesting one in which the author enumerates various classes of problems

remaining to be solved; and, in some instances, he suggests bases for their solution. Observational classification schemes of OH sources are paired with theoretical pumping schemes in a most interesting way. Finally, Professor Cook tries briefly to fit celestial masers into a wider picture of the star formation process.

*Celestial Masers* is a book that many will find interesting and stimulating. I

highly recommend it. Unfortunately, it does contain a few typographical errors in both references and equations, but the reader will readily recognise and easily correct these very minor blemishes. □

*Harold Weaver is Professor of Astronomy at the University of California at Berkeley, and was the Founder-Director of the Radio Astronomy Laboratory at Hat Creek.*

## Nuclear shapes and sizes

C. J. Batty

*Nuclear Sizes and Structure.* By R. C. Barrett and Daphne F. Jackson. (Clarendon: Oxford, 1977.) Pp. 566. £17.50.

In his classic paper on the scattering of alpha particles at large angles, Rutherford wrote: "Considering the evidence as a whole, it seems simplest to suppose that the atom contains a central charge distributed through a very small volume, and . . .". And so we had the first insight into the structure of the atom with its central charged nucleus, later shown to consist of (uncharged) neutrons and (charged) protons, surrounded by a cloud of electrons. Since then, our knowledge of the constituents and the structure of the nucleus has advanced rapidly, but this very sentence of Rutherford's also poses more detailed questions. How big is the nucleus? What shape does it have? How are the constituents and the electric charge distributed? And so on.

The study of nuclear sizes, in its widest sense, has remained since those early days at the core of nuclear physics and of studies on the structure of the nucleus. The success, or otherwise, with which nuclear models can make meaningful predictions as to the distribution of charge and nuclear matter in the nucleus has always been a sensitive test of their validity. The study of nuclear shapes and sizes too has always encompassed a very wide range of topics. The charge distribution, and hence the proton distribution, can be sensed with the electron or the muon through the electromagnetic interaction, and we now have quite detailed information available from measurements of electron scattering and with muonic atoms. Study of the matter distribution which is necessary to provide the neutron distribution, requires the use of strongly interacting probes such

as the proton, alpha particle, pion, kaon, and so on; and a much wider range of nuclear scattering and interaction processes are involved. As a result, our knowledge is much less certain and in certain cases ambiguous or downright conflicting.

It is now 16 years since the monograph on *Nuclear Sizes* by L. R. B. Elton appeared, and the intervening years have seen dramatic advances in our knowledge of nuclear shapes and sizes and in the techniques used for their study. This book by Roger Barrett and Daphne Jackson of the University of Surrey is therefore particularly welcome and provides a long needed successor to the earlier monograph.

Over the past few years, it has become clear that the different types of experiments used to look at nuclear sizes probe different regions of the nuclear matter or charge density and hence are sensitive to different parameters or combinations of parameters of the form chosen for the distribution. It has also led to the so-called 'model-independent' analyses in which there is no rigid *a priori* choice of the form for the nuclear distribution and in which the uncertainties in the derived distribution are more clearly seen.

The first chapter of the book, then, deals with these introductory ideas. Various distribution functions and form factors are defined and the ideas of radial parameters and moments introduced. Some useful comparisons are also made between the numerical parameters calculated from a range of neutron and proton distributions.

It might be concluded, so far, that all the advances of recent years have been on the experimental front. This is by no means so, and the second chapter deals with the various current theories of the nuclear matter distribution. After some introductory ideas, the single-particle model is discussed; in this model individual particles move in an averaged phenomenological nuclear potential. As this potential is, in fact, derived from the interactions of all the nucleons in the nucleus, the model lacks self-consistency. This problem is avoided by using the Hartree-Fock method; and an extensive review

of recent calculations is given. Macroscopic models in which the emphasis is on bulk nuclear properties are next discussed, particularly the Thomas-Fermi approximation and the hydrodynamical model; and the chapter then concludes by considering the especial features of calculations for deformed nuclei. Results from the various types of calculations are compared in a number of useful tables and graphs throughout the chapter.

As already mentioned, measurements of electron scattering and with muonic atoms are used to obtain information about the charge distribution in nuclei; and these topics are discussed in the next two chapters. After considering the motion of electrons and muons in an electromagnetic field, the scattering of electrons by the nuclear charge is discussed. Analyses to obtain the charge distribution using either a simple parameterised model or with a 'model-independent' method are next described, together with a brief discussion of the problems raised by analyses for deformed nuclei. Large angle magnetic scattering is also considered, followed by a discussion of dispersion, radiative and straggling corrections.

For muonic atoms, the chapter moves quickly into a discussion of 'model-independent' analyses of the X-ray spectra, the energy levels for deformed nuclei, magnetic hyperfine structure, and isotope, isomer and isotope shifts. Radiative corrections are particularly important in muonic atoms and until recently were the subject of considerable controversy when measurements for high transitions seemed to indicate a disagreement between experimental results and calculations using quantum electrodynamics. Happily, this problem now seems to be resolved and a review of these topics completes the chapter.

The use of optical and X-ray spectral methods to measure isotope and isomer shifts is only very briefly touched on in the next chapter (just ten pages long). This is unfortunate as the topic is of considerable current interest, particularly in view of the increasing use of laser techniques. Also, the following chapter on experimentally derived charge distribution shows that quite a large body of information has been obtained in this way. This latter chapter, as well as including tables on isotope and isomer shifts, also includes tables on charge distributions for a very wide range of nuclei, including deformed nuclei. Inevitably, such information rapidly becomes out of date and the serious researcher will need to go back to the original literature or to other, more extensive, data compilations. Nevertheless, the tables present a great deal of

useful information in a very compact form and include an extensive set of references to enable the reader to dig deeper.

As indicated, the study of the nuclear matter distribution involves the use of strongly interacting projectiles and the derivation of the required information from nuclear scattering or reaction experiments. These topics, which are dealt with in the next two chapters, are inevitably complicated and it is not too surprising that together these two chapters account for almost half the book.

Nuclear scattering is dealt with first. After an introduction to partial wave methods of analysing scattering from a potential and to the various approximations which are used, the formal theory and general properties of the optical model are dealt with. This is followed by a review of the information gained from analyses of nucleon-nucleus scattering. This review is split into three subsections, covering different energy regions, and includes many tables of optical model potentials and parameters. An equally complete review of the scattering of composite projectiles and of the nuclear size information which can be obtained from experiments then follows.

The chapter on nuclear reactions starts with an extensive discussion of inelastic scattering both to resolved final states and then to summed final states; the former gives information principally about particular spectroscopic states and the latter about average nuclear properties. There follows descriptions of the theory and analysis of transfer, knock-out and photonuclear reactions, and finally of alpha decay. Inevitably, any discussion of nuclear reactions also involves problems related to nuclear reaction mechanisms and to the structure of nuclei. The chapter does, however, pay particular attention to the information about nuclear sizes and other closely related nuclear properties which can be obtained in this way.

It was originally thought that measurements on hadronic atoms would be capable of giving clear information on nuclear matter distributions. It turns out, however, that here nature has not been particularly kind. In the case of pionic atoms, the interaction of the pion with the nucleus is complicated by the presence of dominant  $p$ -wave processes, whereas for kaonic atoms the resonance in the kaon-proton system again complicates the analysis of experimental data. It is still hoped, however, that, with our growing understanding of these interactions, it may be possible to obtain nuclear size information; these topics therefore are discussed in chapter 9 of the book.

The final chapter concentrates on processes capable of giving information about the neutron distribution directly rather than through separate measurements of the proton and matter distributions. Available methods for looking at the excess neutrons include studies of Coulomb energy differences or of charge-exchange reactions. Alternatively, the scattering of pions can be measured at energies at which they interact preferentially with neutrons. Pion production, or the interactions of stopping kaons, can also be used, since in both these cases certain processes can only occur through interactions with neutrons.

This chapter-by-chapter review will have indicated the very wide range of topics covered by the book, all of which are related in some way to the question of nuclear sizes. In view of this broad coverage there is inevitably some unevenness in the treatment of the various topics. How much this matters is a matter for individual judgment, which each reader will have to decide for himself in the light of his own special interests.

The book contains a large number of tables and figures of useful data. As already mentioned, a few of the tables will rapidly become out of date. Nevertheless, they comprise a useful collection of information related to nuclear sizes. The book also contains a list of approximately 1,500 references which fill the last 50 pages of the book and which are frequently referred to throughout its pages. This makes the volume particularly useful to the specialist, who will wish to refer to the original literature. It does, however, create the air of an extended review article rather than that of a definitive text which might appeal more to the student approaching the subject for the first time. To some extent, this is due to the authors' determination to include the most recent developments.

Finally, as the authors themselves point out, the past few years have seen an enormous growth in our knowledge of nuclear sizes and in the range of experiments used for their study. The book provides an excellent review of the situation as it was at the time of writing in 1975. The next few years are likely to see an equally rapid progress in both experimental work and in theoretical calculations. It is also likely to see an ever-increasing range of methods in atomic, nuclear and particle physics being used to study the sizes and shapes of nuclei. □

## EVOLUTION AND THE GENETICS OF POPULATIONS Volume 3

*Experimental Results and Evolutionary Deductions*

**Sewall Wright**

This was originally conceived as a three-volume work, but Wright discovered that work in experimental populations had grown so rapidly that an entire volume should be devoted to the subject. A fourth and final volume will therefore cover variability in natural populations and should be available in 1978. This present volume is devoted primarily to experimental studies of populations in the laboratory: first, inbreeding and crossbreeding in plants and in laboratory and domestic animals; then, artificial and natural selection in the laboratory; evolutionary theories in the light of the theory of gene frequencies and experimental studies; genetic load and the evolution of dominance; and finally, an analysis of the patterns of livestock breeds as an intermediate between laboratory and natural populations. July, £24.50.

## MANUAL OF NEOTROPICAL BIRDS Volume 1

*Spheniscidae (Penguins) to Laridae (Gulls and Allies)*

**Emmet R. Blake**

The four volumes of this Manual will treat all recorded species and sub-species of birds from the mainland of both Central and South America, the continental islands and adjacent waters, excluding Mexico, the West Indies, The Galapagos and Falkland Islands. Of the 2300 species (perhaps 8300 sub-species), Volume 1 covers 600 species and about 1500 sub-species of 48 families. 67 drawings, 12 colour plates, 237 maps. September £35.00.

## THE AFRICAN BUFFALO

*A Study of Resource Limitation of Populations*

**A. R. E. Sinclair**

After providing the early history, habitat requirements and environmental physiology of the African Buffalo, Sinclair seeks to establish what factors determine the size of animal populations, whether population regulation is occurring and, if so, what causes it. His work is supported by extensive field research and detailed information collected between 1965 and 1973. 39 tables, 120 photographs and drawings. June £16.80.

W. John Smith

**Behaviour of Communicating***An Ethological Approach*

Detailed analysis of observed display repertoires illuminates the theoretical discussion that forms the core of this book. Virtually all animal displays transmit messages about the communicator, not the environment, and the next behaviour to be selected. After developing the concept of messages, their form and function in animal communication, and the evolution of display behaviour, Smith takes the discussion into the realm of nonverbal human communication. £13.65.

Stephen Jay Gould

**Ontogeny and Phylogeny**

What is the relation between individual development (ontogeny) and the evolution of species and lineages (phylogeny)? In this, the first major book on the subject in fifty years, the author documents the history of the idea of recapitulation from its first appearance among the pre-Socratics to its fall in the early 20th century. Turning to modern concepts (heterochrony, changes in developmental timing; neoteny, the opposite of recapitulation) Gould demonstrates that even though the whole subject of parallels between ontogeny and phylogeny fell into disrepute it is still one of the great themes of evolutionary biology. Belknap £12.95.

Richard W. Burkhardt Jr

**The Spirit of System***Lamarck and Evolutionary Biology*

This book examines the origin and development of Lamarck's whole theory of organic evolution, the major theory prior to Darwin's. It focuses on the scientific role Lamarck defined for himself and the factors that inspired his belief in organic mutability. His career is described within the aura of French science at the turn of the 18th and 19th centuries, its revolutionary ideas and its political machinations. Lamarck's influence on modern biology is shown in the notorious Lysenko and Kemerer affairs. £11.55.

## Nature of lethality of *t* mutations in embryos

Linda R. Wudl\* Michael I. Sherman\* & Nina Hillman†

*Mutations in the genes of the T complex in mice can lead to death at various stages of embryogenesis. It has been suggested that the T genes specify cell surface antigens which are essential for normal organisation of certain cells within the embryo. But, there is now evidence that at least some of these T complex mutations are simply generalised cell lethals.*

THE set of genes in the mouse known as the 'T complex' has been studied extensively for many years. However, there is still disagreement on both the genetics and the biochemistry of this system. The confusion arises in attempts to explain how apparently single genetic alterations can result in multiple phenotypic effects. Such alterations in the T region, conventionally referred to as recessive (*t*) mutations, may cause (1) death of homozygous embryos at characteristic stages, (2) taillessness when combined with the Brachyury (*T*) mutation in a compound heterozygote (*T/t*), (3) non-Mendelian inheritance from the male parent, (4) suppression of recombination over a rather large region of chromosome 17 (extending, in the case of *t<sup>w5</sup>*, from the centromere to well beyond the H-2 region) and, (5) male sterility when combined with other, complementary, *t* mutations (*t<sup>x</sup>/t<sup>y</sup>*)<sup>1,2</sup>. Present knowledge of the genetics of the T region indicates that although a single mutagenic event may have resulted in what is called the '*t* mutation', a large portion of the genome and multiple loci are affected<sup>1,2</sup>. We shall discuss only the lethal effects of mutation in the T region and the relationship between the *t* genes (or gene) and the programme for early embryonic development.

Two theories have been put forward to explain the lethality of *t* mutations. The first, and most widely quoted, of these proposes that the primary lesion is an alteration at the surface of certain embryonic cells which prevents the cell-cell recognition and interaction required for tissue formation ('organisational failure' hypothesis)<sup>1-6</sup>. The affected embryo becomes disorganised and is resorbed in the uterus. The second theory is simply that, at least for some *t* mutations, all cells of the embryo are adversely affected and that death of the embryo is due to generalised cell lethality<sup>7-11</sup>.

In earlier studies<sup>11</sup>, we tested the organisational failure hypothesis by monitoring the behaviour of mutant embryos *in vitro*. In our culture conditions<sup>12,13</sup>, the organisation and interactions of different cell types are less important for cell survival than they are *in utero*. This is documented by our success in establishing a number of cell lines from cultured blastocysts even though several cell types (for example, embryonic ectodermal derivatives) either degenerate soon after formation or are never produced. In fact, the cell types that develop most reliably in our cultures are extraembryonic endoderm and trophoblast<sup>13</sup>; these are the very cell types that seem to survive longest *in utero* in conceptuses homozygous for every lethal *t* allele<sup>2</sup> with the possible exception of *t<sup>w73</sup>* (ref. 14). Consequently, our *in vitro* techniques should have enabled us to recover those cells from homozygous *t*-mutant embryos that are presumably not directly affected by the mutation. However, when we tested homozygous *t<sup>w5</sup>* mutant embryos<sup>11</sup>, we found that none of the cells was capable of surviving *in vitro*, and indeed, most of the

cells had died at the time of the normal lethal period for *t<sup>w5</sup>/t<sup>w5</sup>* embryos *in utero* (7-10th day of gestation<sup>15</sup>). Furthermore, when pairs of embryos are combined to form chimaeras, homozygous mutant cells in the mosaic embryos do not seem to be rescued by contact with their normal neighbouring cells; in other words, the *t<sup>w5</sup>* mutation behaves as a generalised cell lethal and not as an organisational lethal<sup>11</sup>.

Investigators studying the extrauterine development of embryos bearing two other recessive *t* mutations, *t<sup>6</sup>* (ref. 16), which causes death earlier than *t<sup>w5</sup>*, and *t<sup>w18</sup>* (ref. 17), which leads to embryonic failure at later stages, have come to conclusions different from those we have drawn on the basis of experiments with *t<sup>w5</sup>*. Erickson and Pedersen<sup>18</sup> reported that the inner cell mass (ICM) of presumptive *t<sup>6</sup>/t<sup>6</sup>* blastocysts showed a rapid degeneration *in vitro* while the trophoblast remained viable. They concluded, therefore, that the adverse effects of the *t<sup>6</sup>* mutation were selective for the ICM moiety of the embryo. Artzt and Bennett<sup>19</sup> transplanted 9th d presumptive *t<sup>w18</sup>/t<sup>w18</sup>* embryos under the testis capsule of adult mice and proposed, from analyses of the resultant growths, that ectodermal derivatives of these embryos were capable of surviving whereas mesodermal elements failed to develop. We report here the results of our studies on the development of *t<sup>6</sup>/t<sup>6</sup>* blastocysts both in culture and in an ectopic site. These studies were undertaken to determine whether any cells from the mutant embryos stand a better chance of survival in these experimental conditions than they do *in utero*. We have also assessed the behaviour of *t<sup>w18</sup>/t<sup>w18</sup>* embryos *in vitro*.

### Behaviour of *t<sup>6</sup>/t<sup>6</sup>* embryos *in vitro*

An analysis of the male transmission frequency of the *t<sup>6</sup>* mutation is shown in Table 1a. By the use of these data, we can deduce the percentage of blastocysts with the *t<sup>6</sup>/t<sup>6</sup>* genotype in our cultures (Table 1b). The ICM cells in *t<sup>6</sup>/t<sup>6</sup>* embryos behave under our culture conditions as observed by Erickson and Pedersen<sup>18</sup> in their experiments: by the 7th EGD (equivalent gestation day, that is the age of the embryos had they been left *in utero*), all ICM cells in 35% of the embryos had disappeared, suggesting that more than 80% of the *t<sup>6</sup>/t<sup>6</sup>* embryos contained only trophoblast. By the 8th EGD, all homozygous mutant embryos seem to have lost their ICM (Table 1c).

When we examined the trophoblast moiety of presumptive *t<sup>6</sup>/t<sup>6</sup>* embryos, however, we could see that they too had been affected by the mutation. In all control blastocyst outgrowths containing an ICM, and in the occasional blastocyst outgrowth which had lost its ICM by the 8th EGD, the trophoblast cells had proceeded to polyploidise and become giant. By contrast, the trophoblast cells of presumptive *t<sup>6</sup>/t<sup>6</sup>* blastocyst outgrowths did not become giant<sup>2</sup>.

In a subsequent series of experiments, we generated trophectodermal vesicles from disaggregated blastomeres of normal and *t<sup>6</sup>/t<sup>6</sup>*

\*Roche Institute of Molecular Biology, Nutley, New Jersey 07110

†Department of Biology, Temple University, Philadelphia, Pennsylvania 19122

**Table 1** Transmission frequency distortion of the  $t^6$  allele and behaviour of blastocysts bearing the  $t^6$  mutation in culture

a Transmission frequency of the $t^6$ mutation							
Genotype at T region of animals mated female male (+/+) × ( $T/t^6$ )		Number of offspring  1,656	Number of offspring with normal tails  1,318		Transmission frequency of $t^6$  79.6%		
b Expected proportions of genotypes in mixed embryo populations							
Cross	Genotype at T region of animals mated female male	% of embryos with genotype					
Control	(+/+) × (+/ $t^6$ )	+/+	+/t <sup>6</sup>	$t^6/t^6$			
Experimental	(+/ $t^6$ ) × (+/ $t^6$ )	20.4	79.6	—			
		10.2	50.0	39.8			
c Survival <i>in vitro</i> of ICM cells in embryos carrying the $t^6$ mutation							
Genotype at T region of animals mated	Number of blastocysts cultured	7th EGD*		% of ICMs surviving 8th EGD		11th EGD	
(+/+) × (+/ $t^6$ )	432	observed	expected†	observed	expected†	observed	expected†
(+/ $t^6$ ) × (+/ $t^6$ )	503	96.3	—	95.4	—	91.2	—
		65.2	58.0	54.5	57.4	47.4	54.9

In *a*, to determine transmission frequency, wild-type (SWR/J) females were mated with tailless males. Offspring of genotype +/ $t^6$  were normal-tailed (and were used in the experiments in *c*), while T/+ progeny were short-tailed. Part *b* of the table, based on the data in part *a*, gives the expected proportions of genotypes of the embryos used in *c*. In *c*, embryos were removed at the blastocyst stage, on the fourth day of pregnancy, washed, and cultured individually in NCTC-109 medium supplemented with 10% heat-inactivated fetal calf serum and antibiotics as described by Wudl and Sherman<sup>11</sup>. They were scored for the presence or absence of inner cell mass derivatives with phase contrast optics.

\*EGD, equivalent gestation day, that is, the age of the embryos had they been left *in utero*.

†Expected values if ICM cells are absent in all  $t^6/t^6$  embryos and if ICMs of heterozygous and wild-type embryos in the control and experimental populations survive with the same frequency.

mutant embryos<sup>20,21</sup>. Generally, at a time when control embryos have formed mature blastocysts, trophoblastic vesicles contain only a single layer of trophoblastic cells, that is they are devoid of ICM cells. When trophoblastic vesicles are placed in the appropriate culture medium, they become attached to the substratum and give rise to outgrowths of trophoblastic cells which are capable of differentiation as determined by morphological and biochemical criteria<sup>21,22</sup>. We studied one of these criteria, polyploidisation, in outgrowths from normal and presumptive  $t^6/t^6$  trophoblastic vesicles by monitoring the nuclear diameters of trophoblastic cells. (We have shown elsewhere<sup>23,24</sup> that DNA content in polyploid trophoblastic cells is proportional to nuclear size.) Approximately 40% of trophoblastic vesicles from the experimental cross (see Table 1) gave rise to trophoblastic cells which possessed few or no giant nuclei (for example, Fig. 1, *a*, *c*, *e*, *g*) before death on or about the 12th EGD. On the other hand, in the control cross, which yields only heterozygous and wild-type embryos, all trophoblastic vesicles gave rise to polyploid trophoblastic cells by the 8th EGD (for example, Fig. 1, bottom photos). Non-mutant trophoblastic cells survived longer than the arrested cells in the  $t^6/t^6$  trophoblastic outgrowths (Fig. 1, *g*, *h*). A detailed quantitative analysis of these experiments, to be presented elsewhere (L.W. and M.I.S., in preparation), indicates that trophoblastic vesicles from normal (+/ $t^6$  and +/+) embryos in the experimental cross polyploidise to the same degree as their counterparts in the control cross.

**Table 2** Incidence of haemorrhagic nodule formation in kidneys bearing implants of blastocysts from control and experimental crosses

Cross	No. of blastocysts implanted	No. of kidneys containing nodules	% observed	% expected
Control (+/+) × (+/ $t^6$ )	68	43	63	—
Experimental (+/T $t^6$ ) × (+/ $t^6$ )	63	28	44	38

Fourth day blastocysts were removed from uteri and placed in culture. Within six hours, blastocysts were transplanted individually under the capsule of the left kidney of adult male siblings. Kidneys were scored macroscopically for the presence of haemorrhagic nodules. The percentage of growths observed in the control and experimental crosses was significantly different by  $\chi^2$  analysis ( $\chi^2 = 7.25$ ,  $P < 0.01$ ). The percentage of growths in the experimental cross observed and expected (assuming that all  $t^6/t^6$  embryos will fail to produce growths and that the transmission frequency for the  $t^6$  allele is 79.6%) was not significantly different ( $\chi^2 = 0.74$ ,  $P = 0.5$ ).

The obvious interpretation of these results is that trophoblastic cells are affected by the  $t^6$  mutation, contrary to the report of Erickson and Pedersen<sup>18</sup>; furthermore, the arrest of  $t^6/t^6$ , but not normal, cells in these experiments renders it unlikely that mutant trophoblastic cells fail through a lack of interaction with other cells, since there are no cells other than trophoblastic in trophoblastic vesicle outgrowths. Organisational failure is thus an inadequate explanation of the adverse effects of the  $t^6$ , as well as the  $t^{w5}$ , mutation.

We have now begun to monitor  $t^6$  mutant trophoblastic cells for production of other markers of differentiation. We found (L.W. and M.I.S., in preparation) that presumptive  $t^6/t^6$  trophoblastic cells possess plasminogen activator activity during the period in which normal trophoblastic cells produce and secrete this enzyme<sup>22,25</sup>. They also convert pregnenolone to progesterone, indicating that they possess the enzyme  $\Delta^5$ , 3 $\beta$ -hydroxysteroid dehydrogenase, as do normal trophoblastic cells<sup>24,26</sup>. These results suggest that the individual elements of the developmental programme of trophoblastic cells may be regulated separately, and that mutation in the T region may interfere selectively with some developmental processes, but not others.

### Behaviour of $t^6/t^6$ embryos in an ectopic site

Although all cells from  $t^6/t^6$  embryos are adversely affected by the mutation in culture, some cells from presumptive  $t^{w18}/t^{w18}$  embryos implanted under the testis capsule survive for times longer than the gestation period<sup>19</sup>. It is, therefore, possible that  $t^6$  and  $t^{w18}$  mutations differ, either in type or in severity. Alternatively, one might argue that ectopic sites provide a rich environment for growth of embryonic cells, allowing proliferation of genotypically mutant cells that do not require wild-type T-gene products for survival and growth, whereas our culture conditions might be detrimental to all homozygous  $t$ -mutant cells. To distinguish between these possibilities, we implanted blastocysts from  $t^6$  control and experimental crosses under kidney capsules of immunologically appropriate host mice, and inspected the kidneys of these animals for ectopic growths 14 d later (Table 2). We found that the blastocysts from the experimental cross gave rise to a significantly lower proportion of growths visible under the dissecting microscope as haemorrhagic nodules when compared with blastocysts from the control cross. In fact, the observed number of growths was not significantly different from that expected if all  $t^6/t^6$  embryos had failed to survive the 14-d period under the kidney capsule. The size of the nodule varied from one

**Fig. 1** Behaviour of mutant ( $t^6/t^6$ ) and normal ( $+/+$ ,  $+/t^6$ ) trophoblast cells developing from trophoblastic vesicles. Trophoblastic vesicles were generated by disaggregating 4- and 8-cell embryos<sup>21</sup> from control ( $+/+ \times +/t^6$ ) and experimental ( $+/t^6 \times +/t^6$ ) crosses and culturing individual blastomeres from 4-cell embryos and pairs of blastomeres from 8-cell embryos in Whitten's modified ovum culture medium<sup>33</sup>. After 48 h (5th EGD), structures scored as trophoblastic vesicles were placed individually in serum-supplemented NCTC-109 medium<sup>11</sup>. Trophoblast cells outgrowing from a presumptive mutant ( $a, c, e, g$ ) and a normal ( $b, d, f, h$ ) trophoblastic vesicle were photographed sequentially on the 7th ( $a$  and  $b$ ), 8th ( $c$  and  $d$ ), 9th ( $e$  and  $f$ ) and 11th ( $g$  and  $h$ ) EGD using phase contrast optics. Magnification is the same in all photographs. Scale bar (in  $a$ ), 50  $\mu$ m.

implant to the next, but the range of sizes was the same in the experimental and control crosses.

Approximately half of the kidneys receiving implants of blastocysts were processed histologically and analysed by light microscopy (Table 3) to determine whether we might have missed viable  $t^6/t^6$  ectopic growths either because they were much smaller than those caused by normal embryos or because they were devoid of functional trophoblast cells and, therefore, non-haemorrhagic. In either case, the growth might not be discernible when the kidneys were examined macroscopically. The histological studies also enabled us to compare growths from experimental and control blastocysts to determine whether the growths from one cross might contain cell types not present in growths from the other. We found, however, that virtually all kidneys judged to be positive by the presence of a macroscopic haemorrhage contained extravasated blood, large numbers of giant trophoblast cells, both mononucleated and multinucleated, and extraembryonic endodermal cells.

In several of the explants, the endodermal cells were associated with an amorphous eosinophilic material that has been described by other investigators<sup>27-29</sup> as Reichert's membrane.

No other recognisable embryonic tissues or organs were found in any of the haemorrhagic nodules at the time of autopsy. However, the extensive growth of trophoblast cells and identification of extraembryonic endoderm attest to the presence in the growths, at least initially, of ICM cells<sup>29,30</sup>. In all of the growths, some scattered necrotic cells were present, and these might have been of ICM origin. Fibroblastic cells were commonly observed around the periphery of the growths, and, less frequently, in the central blood cavity. It is assumed that these cells were of maternal origin. In about 40% of the cases in both experimental and control crosses, the trophoblast cells were actively invasive and phagocytosed kidney cells could be seen in the giant cell cytoplasm; the

**Table 3** Histologic analyses of kidneys receiving implants of normal and mutant ( $t^6/t^6$ ) blastocysts

Cross	No. analysed	Macroscopic positives		Macroscopic negatives	
		No. containing trophoblast and extra-embryonic endoderm cells	No. containing Reichert's membrane-like material	No. analysed*	No. containing growths
Control ( $+/+$ ) $\times$ ( $+/t^6$ )	16	15†	7	15	0
Experimental ( $+/t^6$ ) $\times$ ( $+/t^6$ )	17	17	6	15	1

After the kidneys referred to in Table 2 were inspected macroscopically for the presence of growths, they were placed in neutral buffered formalin, embedded in paraffin and serially sectioned (8  $\mu$ m). After dehydration in a graded series of alcohol, the sections were stained with Delafield's haematoxylin and eosin.

\*Entire kidneys were prepared as described above and every section was scanned with low power optics.

†One nodule, which was very large, was only partially sectioned. Those sections inspected contained only blood cells and extraembryonic endoderm cells.

**Table 4** Survival *in vitro* of embryos carrying the  $t^{w18}$  mutation

Cross	Expected % of homozygous mutant embryos	No. of blastocysts cultured	% of blastocysts surviving 22–24th EGD	
			observed	expected*
Control (+/+) × (+/ $t^{w18}$ )	0	404	55.0	—
Experimental (+/ $t^{w18}$ ) × (+/ $t^{w18}$ )	28.7†	402	51.5	39.2

The +/ $t^{w18}$  mice were generated by selecting normal-tailed offspring from the cross of SWR/J females (wild-type in the T region) with  $T/t^{w18}$  males (obtained from Dr Karen Artzt, Sloan Kettering Institute for Cancer Research).

\*Expected incidence if all  $t^{w18}/t^{w18}$  embryos fail to survive the gestation period *in vitro*.

†The proportion of homozygotes is low for  $t^{w18}/t^{w18}$  embryos because the  $t^{w18}$  allele does not show substantial transmission frequency distortion<sup>17</sup>.

remainder of the growths did not seem to be invasive at the time of autopsy, but rather caused a depression of the host tissue at the site of transplantation. Of 30 kidneys scored as negative macroscopically, all but one proved to be negative upon microscopic examination. The exceptional kidney contained a large, subcapsular growth, which was non-haemorrhagic and non-invasive. It lacked trophoblast giant cells and extraembryonic endoderm, containing instead epithelial cells which appeared to be embryonic in nature, some of which were arranged cylindrically, reminiscent of neural tubes. Although this kidney was in the 'experimental' group, we have no way of knowing whether it had received a  $t^6/t^6$ , a +/ $t^6$  or a +/+ blastocyst. In fact, we cannot say for certain whether this growth originated from the implanted blastocyst or whether it developed spontaneously.

The most likely explanation of these observations is that normal (+/+, +/ $t^6$ ) blastocysts, whether from the experimental or the control cross, give rise to the same kinds of growth under the kidney capsule, while all cells from  $t^6/t^6$  blastocysts die within the two week incubation period.

### Behaviour of $t^{w18}/t^{w18}$ embryos *in vitro*

As the results in Table 4 illustrate, over 50% of individually cultured control blastocysts from a population consisting of approximately equal numbers of +/+ and +/ $t^{w18}$  embryos give rise to cells which survive longer than the normal gestation period. Similarly, blastocysts from the experimental cross show approximately the same survival frequency. The implication from these results is that at least some cells from many of the cultured  $t^{w18}/t^{w18}$  blastocysts are viable well beyond the normal period of lethality of homozygous mutant embryos *in utero* (that is about the 9th day of gestation), a finding consistent with the ectopic implant studies<sup>19</sup>. Inspection of the cultures after three weeks (and at later times) did not reveal the presence of cells in the experimental cross population which were morphologically distinguishable from cells in the control cross population. Several of the single blastocyst-derived cultures from both the experimental and control crosses have been maintained *in vitro* for several months, and experiments are in progress to determine their genotype.

### Conclusions

According to the organisational hypothesis,  $t$  mutations "affect discrete steps in development by impairing the differentiation of particular embryonic cell types"<sup>14</sup>, presumably by interference with "processes necessary to cell-cell interaction and determination"<sup>1</sup>. The experiments described above, as well as others already published<sup>7–11</sup>, are inconsistent with this hypothesis, at least insofar as three classes of early-acting  $t$  mutations ( $t^{12}$ ,  $t^6$ ,  $t^{w5}$ ) are concerned. In each case, all cells of the embryo, rather than specific cell types, are adversely affected. The facts that cells from  $t^6$ -mutant embryos fail to survive in ectopic sites as well as in culture, and that some cells from  $t^{w18}$ -mutant embryos seem to survive under both conditions, reduces the possibility that the observed generalised effect of early-acting  $t$  mutations is due to inadequate culture conditions. Our observations with  $t^6$ -mutant embryos also argue against impairment of all differentiation in affected cells, since  $t^6/t^6$  trophoblast cells, clearly abnormal in that they fail to endoreduplicate like their normal counterparts,

nevertheless, express characteristic differentiation markers (plasma-activator,  $\Delta^5$ , 3  $\beta$ -hydroxysteroid dehydrogenase). Furthermore, the block to endoreduplication is unlikely to be related to improper cell-cell interaction, either self or non-self, since we have found that normal trophectoderm cells are capable of initiating and continuing endoreduplication, even when isolated as single cells (S.B. Atienza and M.I.S., unpublished observations).

It is difficult to place the observed alterations in surface antigens of  $t$ -mutant sperm<sup>3</sup> and embryos<sup>3,17</sup> into perspective with our observations because unequivocal evidence has not been presented to indicate whether such antigens are primary  $t$ -gene products, secondary effects resulting from mutation in the T region, or products of genes closely linked to the T complex which seem to be part of it due to suppression of recombination. Of course, surface alterations can lead to cell lethality in ways other than those involving faulty cell-cell interactions; for example, they might interfere with intracellular processes such as those related to replication and the cell cycle<sup>32</sup>.

We do not yet know why some cells in embryos homozygous for later-acting  $t$  mutations are able to survive and proliferate while all cells in early-acting  $t$ -mutant embryos die. It may be that some cells at advanced stages of differentiation do not express the altered product(s) or require the wild-type product(s) of the T-complex genes. We stress, however, that there is a danger in making comparisons between the various classes of lethal  $t$  mutations until more is learned about the number and nature of genes in the T complex.

## Transformation of the state of nitrogen in diamond

R. M. Chrenko, R. E. Tuft & H. M. Strong

General Electric Corporate Research and Development Schenectady, New York 12301

*High temperature-high pressure annealing experiments on diamond transform type IB dispersed nitrogen into type IA aggregate nitrogen. The activation energy for the transformation is approximately  $60 \text{ kcal mol}^{-1}$  (2.6 eV). An estimate is given for the diffusivity of nitrogen in diamond for this transformation*

NITROGEN impurity is found in substitutional lattice positions in most natural and synthesised diamonds, but its usual state differs in the two types of diamond. Most natural diamonds that contain nitrogen have it in a form that is inactive to electron paramagnetic resonance (EPR) and these diamonds have been classified type IA. In the past this form of nitrogen has been pictured as localised in the platelets characteristic of type IA crystals, but evidence suggests the nitrogen may occur in clusters of 10–13 atoms<sup>1</sup> or substitutional nitrogen pairs<sup>2</sup> rather than in platelets. Nitrogen in synthesised diamonds is EPR active and atomically dispersed. These diamonds have been placed in the type IB classification.

A few natural diamonds are type IB or a mixture of types IA and IB. No synthesised diamonds with wholly type IA properties have been made, but some type IA characteristics in certain synthesised diamonds have been reported<sup>3,4</sup>.

The existence of the two diamond types poses questions about their relative stability and whether the stable type may be formed by a high temperature-high pressure treatment in the laboratory. If successful, this might provide an insight into the history of natural diamonds and give important information for understanding their growth mechanisms. For example, Klyuev *et al.*<sup>3</sup> and Evans<sup>5</sup> suggested that nitrogen deposits in the atomically dispersed state (type IB) in natural diamond during growth, with the type IA state forming during the long residence in the high temperature environment deep within the earth. Is this hypothesis consistent with experimental data and could approximate residence times be ascertained?

Our experiments have indicated high temperature-high pressure treatment transforms type IB nitrogen into type IA nitrogen. This has provided information about the reaction rates for the transformation IB to IA and the diffusivity of nitrogen in diamond. Some implications are drawn from the data about the growth of natural diamonds. More experiments should clarify some old questions about platelets, X-ray spikes, and gem manufacturing.

### Experimental methods

The difficult experimental conditions necessary for transforming nitrogen states in diamond are dictated by the extraordinary refractory nature of diamond as shown by its high melting point and resistance to plastic flow. The melting point is about 4,000 K at 150 kbar (ref. 6) and no plastic yielding occurs below about 2,073 K (ref. 7). Hence, any process requiring lattice diffusion of nitrogen could not be expected to proceed rapidly below temperatures of about 2,000 K. These experiments were conducted at this temperature level under pressures in the range 55–65 kbar to prevent graphitisation of the diamonds.

The GE 'Belt' pressure apparatus<sup>8</sup> was used to provide the

pressurised environment for the diamond heat treating experiments. The crystals to be heated, 1–2 mm in size, were placed in a small cavity in the centre of a 3.17 mm diameter graphite rod (Fig. 1). The temperatures reached in terms of power input were measured several times with a 0.127 mm Pt–Pt 10% Rh thermocouple. Temperatures in terms of power input were consistent to within about  $\pm 75^\circ$  at the 2,273 K level. Part of the variation from one test to another was due to the differing cross sections of the crystals used. This variation influenced the heating current density in the graphite rod at the diamond where its cross section was reduced by different amounts due to the presence of diamond of different sizes.

Crystals were treated at temperatures between 1,873 K and 2,273 K, usually for 30 min at a time, at pressures near to or within the region for the thermodynamic stability of diamond at the treatment temperature, 55–65 kbar.

The analytical techniques used to monitor the conversion of the nitrogen from the IB to IA state were dictated by the characteristic properties of each state. Type IA and type IB nitrogen each induce their own characteristic ultraviolet, visible, and infrared absorptions; type IA nitrogen is apparently EPR inactive but type IB nitrogen is EPR active. Many type IA diamonds are colourless whereas most type IB crystals are canary yellow.

Quantitative measurements of types IA and IB nitrogen concentrations depend on the infrared absorption intensities of bands at  $1,280 \text{ cm}^{-1}$  for the type IA nitrogen and at  $1,130 \text{ cm}^{-1}$  for type IB nitrogen. These two band systems have been closely correlated with nitrogen content by Kaiser and Bond<sup>9</sup> for type IA nitrogen and Chrenko, Strong and Tuft<sup>10</sup> for type IB nitrogen. Absorption spectra recorded for each crystal before and after heat treatment provided information on the amounts of each type of nitrogen present and the total in the crystal in these two states. Any change in this nitrogen total would indicate either a change in the amount of nitrogen in the crystal or a transformation to some other state not yet identified.

EPR was used in a semi-quantitative manner. The decrease in integrated intensity (amplitude  $\times$  width<sup>2</sup>) of the centre line of the dispersed nitrogen hyperfine triplet was a measure of the decrease

Fig. 1 Sample holder for diamond used in the high pressure apparatus. The alumina liner protected the pyrophyllite sample holder from the high core temperature. The thermocouple was used in several experiments for calibration of temperature in terms of power input. For most annealing experiments the thermocouple was left out.

in dispersed nitrogen content. The intensities were normalised to unit intensity for the untreated crystal.

The ultraviolet and visible absorptions were not very useful for quantitative measurements because the absorption occurs in a poorly defined absorption tail. The increased transmission in the 350–500 nm region and emergence of the 415.2 nm zero phonon line of the N-3 absorption system, however, were characteristic of the transformation from type IB to IA diamond. These latter measurements therefore, confirmed that the type IB to type IA transformation was occurring.

## Results

After heat treatment, the deep yellow colour of type IB crystals had faded significantly. Quantitative measurements on their spectral absorption and EPR characteristics yielded data on the transformation from IB to IA that are summarised in Table 1.

Infrared absorption spectra for a synthesised type IB crystal, before and after heat treatment at 2,173 K for 30 min, are shown in Fig. 2. A natural type IA crystal absorption spectrum is included for comparison. The partial conversion of the type IB crystal to type IA is evident.

The quantitative measurements from infrared absorption data showed that concentrations of type IB nitrogen decreased while the concentrations of type IA nitrogen correspondingly increased. The total nitrogen remained constant. Measurements of type IB nitrogen were actually made using the absorption at 1,343 cm<sup>-1</sup>, which is correlated with the 1,130 cm<sup>-1</sup> absorption, since the 1,130 cm<sup>-1</sup> absorption becomes difficult to resolve as it weakens while the 1,343 cm<sup>-1</sup> absorption remains sharp and distinctive. Type IA nitrogen concentrations were obtained from its 1,280 cm<sup>-1</sup> absorption. The EPR data showed close agreement with infrared absorption data on decreases in concentrations of type IB nitrogen. The ultraviolet-visible data indicated increased transmission in the 350–500 nm region with the transformation IB to IA nitrogen, in agreement with the quantitative measurements on the transformation. In the samples wherein sufficient conversion had taken place, the 415 nm zero phonon line of the N-3 system of type IA diamonds appeared, confirming the previous evidence on the nature of the transformation.

Heat treatment of type IB synthesised crystals at 2,273 K produced only the type IA group A bands characterised by the absorption at 1,280 cm<sup>-1</sup>. No evidence was seen for the group B bands, whose strongest absorption is at 1,175 cm<sup>-1</sup>. Also, heat treatment at 2,273 K of a natural diamond having both the 1,280 cm<sup>-1</sup> and 1,175 cm<sup>-1</sup> group A and group B absorptions produced no shift in relative intensities of either band.

Quantitative measurements on the extent of the reaction in terms of time and temperature indicated that the transformation was controlled by second order diffusion kinetics obeying the rate equation:

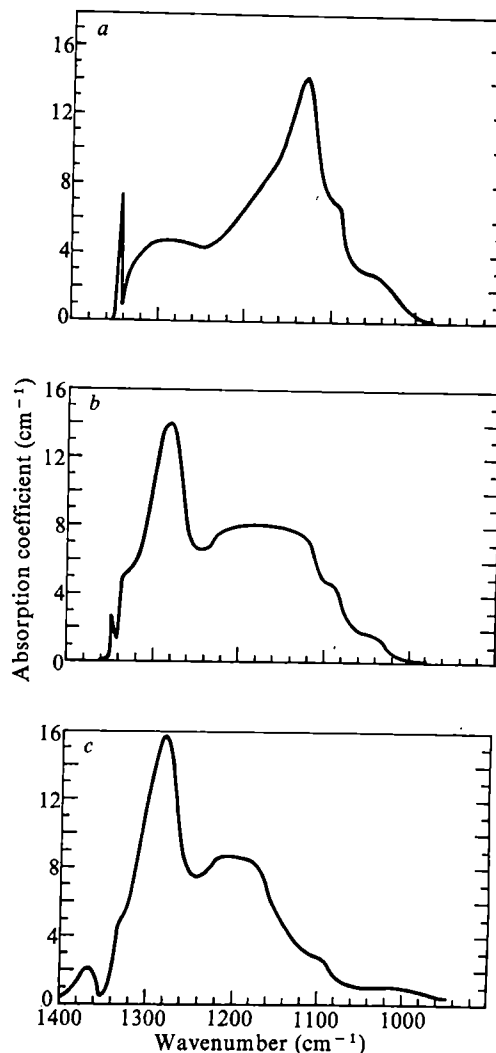

$$kt = 1/c - 1/c_0$$

in which  $k$ , the rate constant, was expressed as min<sup>-1</sup> p.p.m.<sup>-1</sup>;  $t$  is the time in min;  $c_0$  the initial concentration of type IB nitrogen in

p.p.m. and  $c$  the concentration of type IB nitrogen remaining after heat treatment. In Fig. 3,  $1/c$  is plotted against  $t$  for the data at 2,173 K which gives  $k = 1.74 \times 10^{-4}$  min<sup>-1</sup> p.p.m.<sup>-1</sup>.

An Arrhenius plot for all of the reaction rate data is shown in Fig. 4. The scatter in the data points may be attributed in part to uncertainties in temperature measurement and to the fact that nitrogen can be unevenly distributed within diamond crystals. During growth, nitrogen has a strong tendency to collect in streaks

Fig. 2 Infrared absorption spectra for *a*, a type IB synthesised diamond as grown; *b*, the same diamond after a heat treatment for 30 min under pressure at 2,173 K; *c*, a typical type IA natural diamond, for comparison purposes.

Fig. 3 A plot of  $1/c$  against time in min for a type IB diamond run at 2,173 K.  $c$  is the concentration of type IB nitrogen in p.p.m. A value of  $k = 1.74 \times 10^{-4} \text{ min}^{-1} \text{ p.p.m.}^{-1}$  is obtained from this data.

and patches along certain crystal planes instead of distributing itself uniformly. The infrared and EPR measurements do not differentiate between concentrated and evenly distributed nitrogen. They measure only the total dispersed nitrogen present. Because the apparent reaction rate is proportional to the concentration of dispersed nitrogen the reaction in a concentrated nitrogen streak would be seen as running much faster than it would if the nitrogen were more evenly dispersed.

The reaction rate may also be influenced by the presence of dislocations. Conceivably, certain types of dislocations would facilitate the diffusion of nitrogen in diamond thereby speeding up the formation of type IA nitrogen.

From the Arrhenius plot in Fig. 4, the activation energy for rate constant was found to lie within the range 48 to 73 kcal mol<sup>-1</sup>. Using the equation  $k = A \exp(-E/RT)$ , assuming an activation energy for the reaction rate of 60 kcal mol<sup>-1</sup> (2.6 eV) and a  $k$  value of  $1.74 \times 10^{-4} \text{ min}^{-1} \text{ p.p.m.}^{-1}$  at 2,173 K, a set of  $k$  values for the temperature range 1,573 to 2,273 K was obtained. A table of times for the reaction to reach 50, 99.0, and 99.9% completion at temperatures between 1,573 and 2,273 K was then prepared (Table 2) for an assumed initial concentration of type IB nitrogen of  $c_0 = 500 \text{ p.p.m.}$

These experiments provide an opportunity to obtain some rough estimates on the diffusivity of nitrogen in diamond for the type IB to type IA reaction. This was done by assuming type IA nitrogen to be in the form of clusters and making certain other assumptions about the size and number of clusters formed, as well as the concentration gradient of dispersed type IB nitrogen between clusters.

The calculation for the diffusivity is based on Fick's first law,  $\Delta N = D(dc/dx)At$ ; in which  $\Delta N$  is the number of atoms of

nitrogen in a 1 cm<sup>3</sup> diamond which are collected into clusters,  $D$  is the diffusivity in cm<sup>2</sup> s<sup>-1</sup>,  $dc/dx$  is the concentration gradient expressed as number of atoms  $\times \text{cm}^{-4}$ ,  $A$  the effective diffusion area in cm<sup>2</sup>, and  $t$  the time in s.

The effective diffusion area,  $A$ , was taken as the area of one 13 atom cluster multiplied by the average number of clusters present during the initial 30-min anneal. One cluster was estimated to have the area of a  $4 \times 10^{-8} \text{ cm}$  cube. The example used for calculating  $D$  was taken from Table 1 in which a crystal (S-1) having 365 p.p.m. type IB nitrogen originally was heated for 30 min at 2,173 K and then found to have its type IB nitrogen reduced to 128 p.p.m. Hence, in a 1 cm<sup>3</sup> crystal the number of cluster nitrogen atoms,  $\Delta N$ , would have been  $42 \times 10^{18}$ . The average number of clusters was  $10^{18}$  and the cluster spacing was  $10^{-6} \text{ cm}$ .  $dc/dx$  was assumed to be  $42 \times 10^{18} \text{ cm}^{-3}$  divided by 1/2 the spacing between clusters or  $5 \times 10^{-7} \text{ cm}$ . With these assumptions, the value of  $D$  at 2,173 K is  $\sim 3 \times 10^{-14} \text{ cm}^2 \text{ s}^{-1}$ .

Fig. 4 A plot of  $\ln k$  values against  $10^4/T$  for all the experiments. The slope of the drawn line corresponds to an activation energy of 60 kcal mol<sup>-1</sup>. S, synthesised diamond; N, natural diamond.

This value of the diffusivity of nitrogen in diamond may be compared to the diffusivity of carbon in diamond from data supplied by Swalin<sup>11</sup>. Swalin gave values for  $D_0$  of 11.6 cm<sup>2</sup> s<sup>-1</sup> and  $Q$  of 143 kcal mol<sup>-1</sup> in

$$D = D_0 \exp(-Q/RT)$$

At 2,173 K this gives  $D = 6 \times 10^{-14} \text{ cm}^2 \text{ s}^{-1}$ . Hence, in consideration of the nearly equal sizes of the nitrogen and carbon atoms, a reasonable value for the diffusivity of nitrogen for the type IB to type IA transformation in diamond should be in the order of  $10^{-14} \text{ cm}^2 \text{ s}^{-1}$  at 2,173 K provided that the cluster model for aggregate type IA diamond is correct.

Initial concentration,  $c_0$ , assumed to be 500 p.p.m. type IB nitrogen. Calculations based on:  $k = A \exp(-E/RT)$  with  $E = 60 \text{ kcal mol}^{-1}$  and  $k = 1.74 \times 10^{-4} \text{ min}^{-1} \text{ p.p.m.}^{-1}$  at 2,173 K.

## Conclusions and discussion

At temperatures between 1,873 K and 2,273 K the type IA nitrogen state in diamond is the stable form, not the type IB state. In this temperature region the diamond states responsible for both group A and group B type IA absorption bands seem to be stable. The experiments also suggest that the transformation of dispersed type IB nitrogen into type IA nitrogen is more favourable kinetically than diffusion of dispersed nitrogen out of the diamond.

The activation energy for the type IB to type IA nitrogen transformation is approximately  $60 \text{ kcal mol}^{-1}$  (2.6 eV) over the temperature range 1,873 K to 2,273 K. Assuming a cluster model for aggregate type IA nitrogen, an approximate value for the diffusivity of nitrogen for the type IB to type IA transformation should be in the order of  $10^{-14} \text{ cm}^2 \text{ s}^{-1}$  at 2,173 K.

Continuing studies should give some insight into some old questions about diamonds. For example, it was believed that the platelets seen in type IA diamonds with the transmission electron microscope were composed of a nitrogen-carbon complex. New evidence suggests the platelets are composed of interstitial carbon<sup>5,12</sup>, with nitrogen apparently necessary for the formation of the platelets but not being incorporated into them in any appreciable amount. Transmission electron microscope studies on the present transformed type IB synthesised diamonds should help resolve the role of nitrogen in the formation of platelets. A parallel study on X-ray diffraction spikes should confirm any findings about platelets.

It has been considered that the various optical features of type IA diamond such as the  $1,280 \text{ cm}^{-1}$  absorption band or the N-3 absorption and emission system with its sharp zero phonon line were found only in natural diamonds. Hence, the finding of the N-3 emission system in the Hannay diamonds was taken as proof for their natural origin<sup>13</sup>. This assumption is probably correct since these features are related to aggregate nitrogen and the required annealing conditions for transforming the type IB dispersed nitrogen found in synthesised diamonds into type IA aggregate nitrogen have not been attainable until recently. These annealing conditions were almost certainly not attainable in the laboratory during Hannay's time. Present experiments have shown what these conditions are: 1,673 K at 60 kbar for ~50 d or 1,873 K at 60 kbar for ~7 d for 99% conversion of type IB to type IA nitrogen (see

Table 2). These times and temperatures are appreciably greater than those reported by Hannay<sup>14</sup>. More detailed experiments will be needed to differentiate between natural and synthesised diamonds in the future.

The colouration change that occurs on annealing type IB crystals suggests that large, yellow type IB synthesised diamonds<sup>15</sup> that are grown slowly to obtain gem quality crystals could be turned into colourless crystals by proper annealing.

It now seems quite certain that during the growth of diamond in a nitrogen containing environment, whether naturally or in the laboratory, nitrogen deposits substitutionally in diamond in an atomically dispersed state. With prolonged dwell times in the growth environment, the nitrogen state changes, quite probably forming aggregates which impart characteristic type IA properties.

The time for completion of the reaction is rather short on a geological time scale. The fact that some natural diamonds do contain a substantial amount of atomically dispersed nitrogen suggests that these crystals were exposed to temperatures above 1,300 to 1,500 K for only relatively short times during growth and later transport to the surface through the internal churnings of the mantle.

We thank the General Electric Company Corporate Research and Development Center for supporting this work, and Lazare Kaplan and Sons, Inc. of New York for supplying some of the natural diamonds. H.M.S. is consultant to Lazare Kaplan, having retired from General Electric.

# Terrestrial lead isotopic evolution and formation time of the Earth's core

R. Vollmer

Department of Earth Sciences, University of Leeds, Leeds, UK.

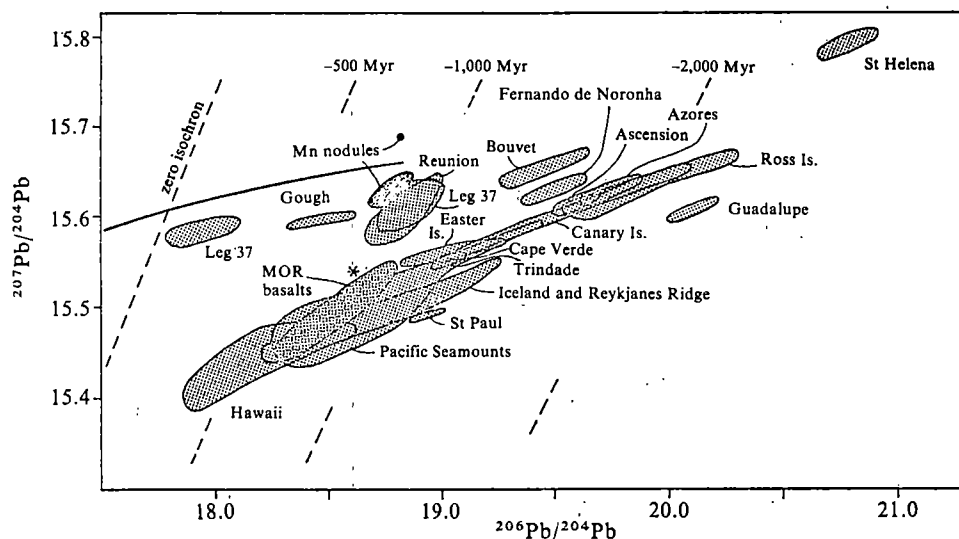

*The radiogenic nature of Pb in average crust and mantle probably requires some interaction between mantle and core during core formation and is thus incompatible with heterogeneous accretion models for the Earth. Pb isotope evolution models for hot and cool accretion indicate that core formation was not quasi-simultaneous with accretion although the core was probably 95% completed within the first 700 Myr of the Earth's history.*

THE high precision Pb isotope data which has become available in the past few years enables average Pb isotopic composition for the sampled mantle and crust (Fig. 1) to be estimated. The mid-oceanic-ridge (MOR) basalts occupy a restricted field, whereas oceanic islands extend linearly to more radiogenic Pb. The most reliable estimate of average crustal Pb is probably given by the present-day ratios of the conformable Pb ore growth curve<sup>1</sup> which represents the Pb isotopic evolution of average crustal Pb<sup>2,3</sup>. Another estimate is obtained from Pb in manganese nodules and

oceanic sediments. This Pb has its origin in continental waters, as seawater has an order of magnitude lower Pb concentrations, and as the mean resident time of Pb in seawater is short (~3,500 yr)<sup>4</sup> it will give the average Pb of the eroded continental surface. There is a good agreement between both estimates (Fig. 1). It is evident from the difference in the <sup>207</sup>Pb/<sup>204</sup>Pb ratio that continental crust, at least in the past  $1 \times 10^9$  yr but possibly from early on in the Earth's history, has followed a different Pb isotopic evolution than oceanic mantle. This precludes a steady growth of the continental crust until the present.

If the crust-mantle U concentration is estimated to be 0.035 p.p.m.<sup>5</sup>, then a  $\mu$  value (<sup>238</sup>U/<sup>204</sup>Pb) of 9.5 will yield 0.0037 p.p.m. <sup>204</sup>Pb. From continental crustal abundances for U of 1.9 p.p.m. (ref. 6) and for Pb of 12.5 p.p.m. (ref. 7), a mass balance calculation gives 32% of U and 27% of Pb in the crust now. Despite uncertainties of up to 50% in some estimates a crustal  $\mu$  value of 11 derived from these figures is in excellent agreement with a present-day  $\mu$  value of 10.75 resulting from the Pb ore growth curve<sup>1</sup>. Although Pb and U are both strongly enriched in the crust, U is probably only slightly enriched relative to Pb. A similar geochemi-

**Fig. 1** Lead isotopic composition of oceanic basalts and manganese nodules. Solid line, conformable lead ore growth curve; \*, estimate of average sampled crust-mantle Pb isotopic composition. Source of data: MOR basalts (ref. 9); oceanic islands (refs 9, 21-25); manganese nodules (refs 26, 27 and R.V. unpublished); conformable Pb ore growth curve (ref. 1); reference isochrons (refs 10, 17).

cal behaviour of U and Pb is demonstrated by only considering oceanic Pb: MOR basalts seem to be derived from a previously depleted source region. They contain low concentrations of LIL (large ion lithophile) elements and contain also less radiogenic Pb (and Sr) than oceanic islands basalts<sup>8,9</sup> (Fig. 1). Enrichment in LIL elements is again correlated with a slight increase in the  $\mu$  value. Because of this geochemical behaviour the best estimate for average oceanic Pb is probably not the average MOR basalt but a point shifted somewhat to the more radiogenic side within the MOR basalt field. From these figures the average Pb isotopic composition for the sampled crust-mantle system is estimated to be  $^{206}\text{Pb}/^{204}\text{Pb} \approx 18.6$  and  $^{207}\text{Pb}/^{204}\text{Pb} \approx 15.54$ .

Comparison with meteoritic Pb (Fig. 1) reveals that the sampled mantle and crust is radiogenic in excess of a single-stage evolution (an evolution with constant U/Pb ratios) dating from  $4.57 \times 10^9$  yr, when the Pb in the Earth had the same isotopic composition as the Pb in meteorites; this time is commonly regarded as the time of accretion of the Earth. This radiogenic nature is particularly pronounced when the revised U decay constants of Jaffey *et al.*<sup>10</sup> are used, and is demonstrated by large negative single-stage model ages from -600 Myr to -1,000 Myr for MOR basalts and ~ -800 Myr for the estimated average sampled crust-mantle system (Fig. 1). This cannot be attributed to uncertainties in the estimated crustal Pb. For the average crust-mantle system to fall on the meteoritic zero isochron, the average crust would have to be extremely unradiogenic ( $^{206}\text{Pb}/^{204}\text{Pb} \sim 14-15$ , corresponding to a model age of ~ 2,500 myr). This would be far beyond the limits of uncertainty in this estimate, and contrary to the observation that U and Pb are on the whole very little fractionated. As it is unlikely that the Earth is substantially younger than meteorite parent bodies (a single-stage evolution, under the condition of a large U-Pb fractionation during accretion, would yield less than 4,420 Myr), it follows, therefore, that the average Pb of the sampled crust-mantle system is almost certainly radiogenic in excess of a closed system evolution. U must have been added and/or Pb been removed from this system sometime during its history since the accretion of the Earth.

It has been postulated that the unsampled (presumably lower) mantle is the source of the excess U. For example, Church and Tatsumoto<sup>9</sup> suggest that mantle convection extends to depth exceeding the pyroxene-garnet transformation, resulting in a strong exclusion of large ion lithophile (LIL) elements from the mantle mineralogy and in their concentration in an interstitial phase. Separation of this interstitial phase would leave the lower mantle depleted and the upper mantle enriched in LIL elements, allowing  $\mu$  to increase with time in the upper mantle. This model, however, is incompatible with a chondritic rare earth abundance pattern for the bulk crust-mantle system. As the source of MOR basalts seems to be depleted in LIL elements and thus in light rare earth elements and has been so for much of the Earth's history<sup>11-13</sup>, the model proposed by Church and Tatsumoto would demand that the lower mantle, and thus the bulk crust-mantle

system be even more strongly depleted in light REE than the source of MOR basalts. This is extremely unlikely.

An obvious, and possibly the only conceivable way a radiogenic crust-mantle system may be generated would be by enrichment in U and depletion in Pb during core formation. This requires some interaction between mantle and core during core formation (but does not necessarily entail equilibrium between core and mantle) and is thus incompatible with, and a strong argument against, a heterogeneous accretion model for the Earth.

In the following, two simple models of core formation based on Pb isotope data are presented. Model 1 is identical with the model of Oversby and Ringwood<sup>14</sup> who start from the same basic premise; however, the revised U decay constants of Jaffey *et al.*<sup>10</sup> will significantly alter the results. In both models it is assumed that all U present in the undifferentiated Earth is accumulated in the mantle and none is retained in the core. This seems to be a reasonable assumption from our knowledge of the chemistry of the core<sup>15</sup>. The Pb partition coefficient between a silicate melt and iron-nickel with minor amounts of sulphide or silicate has been measured by Oversby and Ringwood<sup>14</sup>. Their best estimate for the core-mantle Pb partition coefficient is  $D_{\text{Pb}}^{\text{c/m}} = 2.5 \pm 0.5$  although some uncertainty exists because of the required large extrapolation to high pressures.

## Model 1

The specific boundary condition (in addition to those outlined above) for this model is: the time of core formation is assumed to be short in comparison to that required to change significantly the Pb isotopic composition by decay, so that core formation may be regarded as a discrete and instantaneous process. This approximation is valid if core formation occurred within a few Myr. This will reduce the Pb isotopic evolution to a simple two-stage evolution model with constant  $\mu$  in the first stage, for which is valid<sup>16</sup>:

$$\frac{\mu^{\text{Earth}}}{\mu^{\text{m}}} = \frac{A^{\text{m}} (\exp \lambda' t_c - 1) - B^{\text{m}} (\exp \lambda t_c - 1)}{B^{\text{m}} (\exp \lambda t_p - \exp \lambda t_c) - A^{\text{m}} (\exp \lambda' t_p - \exp \lambda' t_c)} \quad (1)$$

where  $A^{\text{m}} = (^{206}\text{Pb}/^{204}\text{Pb})_0^{\text{m}} - a_p$ ,  $B^{\text{m}} = [(^{207}\text{Pb}/^{204}\text{Pb})_0^{\text{m}} - b_p] / 137.88$ ,  $\lambda$  and  $\lambda'$  are the  $^{235}\text{U}$  and  $^{238}\text{U}$  decay constants, and  $\mu$  is the  $^{238}\text{U}/^{204}\text{Pb}$  ratio normalised for U decay to its present-day value; m and c stand for the average crust-mantle and core, respectively, and  $a_p$ ,  $b_p$  are the Pb isotope ratios at  $t_p$  (the time of accretion of the Earth) derived from meteorite Pb<sup>17</sup>. A relation between the  $\mu$  value for the bulk Earth in the first stage from  $t_p$  till  $t_c$  ( $\mu^{\text{Earth}}$ ) and the average  $\mu$  value for the crust-mantle system ( $\mu^{\text{m}}$ ) in the second stage from  $t_c$  till  $t_0$  (the present) is derived through the crust-mantle U and Pb concentrations  $C_{238\text{U}}$ ,  $C_{204\text{Pb}}$  and partition coefficients  $D_{\text{U}}^{\text{c/m}}$  and  $D_{\text{Pb}}^{\text{c/m}}$ .

$$C_{204\text{Pb}_0}^{\text{Earth}} = C_{204\text{Pb}_0}^{\text{m}} [\beta_0 D_{\text{Pb}}^{\text{c/m}} + (1 - \beta_0)] \quad (2)$$

Fig. 2 Model 1: time of core formation as a function of the core-mantle Pb distribution coefficient.

and because  $D_U^{c/m} = 0$

$$C_{238U}^{Earth} = C_{238U}^m (1 - \beta_0) \quad (3)$$

where  $\beta_0$  is the relative mass of the core at the present ( $\beta_0 = 0.32$ ). Equations (2) and (3) combine to

$$\mu^{Earth} = \frac{\mu^m (1 - \beta_0)}{\beta_0 D_{Pb}^{c/m} + 1 - \beta_0} \quad (4)$$

The results are plotted in Fig. 2. The sum of all uncertainties involved (except uncertainty in the distribution coefficient) may be approximated to be variations in the single-stage model age. The revised U decay constants of Jaffey *et al.*<sup>10</sup> causes a change in the model age by a factor of 2 to 3 and, therefore, the results are significantly different from those obtained by Oversby and Ringwood<sup>14</sup>, who concluded that the time interval between accretion and formation of the core was probably less than 100 Myr and because of such a short interval, accretion must have resulted in a hot initial Earth. Assuming that the U-decay constants (which are the most important source of any uncertainty) will not significantly change with any further revision, core formation according to this model cannot have occurred before 200 Myr and probably not later than 500 Myr after accretion. Values for  $\mu^{Earth}$  are strongly dependent on the assumed Pb partition coefficient: they are about 4.0, 4.8, and 6.5 for  $D_{Pb}^{c/m}$  equal to 3, 2, and 1, respectively. The average  $\mu$ -value for crust-mantle is about 9.4. Contrary to the interpretation given by Oversby and Ringwood<sup>14</sup>, this model is only compatible with an initially solid Earth being heated by radioactive decay until the metallic phase suddenly segregated into a core.

## Model 2

If core formation is regarded as a first-order rate process, the rate of growth of the core is given by

$$\frac{d\beta}{d\tau} = -\frac{d\beta^*}{d\tau} = \varepsilon\beta^* \quad (5)$$

where  $\beta^*$  is fractional mass of core material, which is present at any time in the mantle either as metallic particles, droplets, or in solution, and is equilibrated with the surrounding silicate phase;  $\varepsilon$  is the growth constant for the core. The mass of core at time  $\tau$  is then

$$\beta_\tau = \beta^* (\exp \varepsilon \tau - 1) \quad (6)$$

if it is assumed that at the time of accretion of the Earth the mass of core had been zero. Equation (6) is written in the commonly used geological timescale ( $t$ ) where  $t_0$  is zero and time is counted positive into the past:

$$\beta_t = \beta_0^* (\exp \varepsilon t_p - \exp \varepsilon t) \quad (7)$$

From equation (7) follows the mass of core at time  $t$  in relation to its present mass:

$$\beta_t = \frac{\beta_0 (\exp \varepsilon t_p - \exp \varepsilon t)}{\exp \varepsilon t_p - 1} \quad (8)$$

The concentration  $C_N$  of a nuclide  $N$  in the residual mantle after the  $n$ -th batch of core material,  $\Delta\beta$ , has segregated from it is related to the concentration of the nuclide in the mantle (relative mass:  $1 - \beta$ ) immediately before this event by

$$C_N^m (1 - \beta)_{n-1} = [\Delta\beta D_N^{c/m} + (1 - \beta)_n] C_{Nn}^m \quad (9)$$

where  $D_N^{c/m}$  is the core-mantle distribution coefficient for the nuclide  $N$ . The change in concentration during this event is given by  $\Delta C_N = C_{Nn} - C_{N(n-1)}$  and the change in the relative mass ( $1 - \beta$ ) of the mantle by  $\Delta\beta = (1 - \beta)_{n-1} - (1 - \beta)_n$ . The concentration at time  $t$  is therefore related to the mass of core at time  $t$  by

$$\int_{C_{Ntp}^m}^{C_{Nt}^m} \frac{-d C_N^m}{C_N^m} = (D_N^{c/m} - 1) \int_0^{\beta_t} \frac{d\beta}{1 - \beta} \quad (10)$$

which integrates to

$$C_{Nt}^m = C_{Ntp}^m (1 - \beta_t)^{D_N^{c/m} - 1} \quad (11)$$

The  $\mu$  value of the mantle at  $t$  will be (approximation  $D_{Pb}^{c/m} - C_{Pb}^c/C_{Pb}^m \approx C_{204Pb}^c/C_{204Pb}^m$ )

$$\mu_t^m = \mu_{tp}^m (1 - \beta_t)^{-D_{Pb}^{c/m}} \quad (12)$$

Finally, the growth of radiogenic  $^{206}Pb$  since  $t_p$  is given by

$$\left( \frac{^{206}Pb}{^{204}Pb} \right) - a_p = \int_0^{t_p} \lambda \mu_t^m \exp \lambda t \, dt \quad (13)$$

where  $\mu_t^m$  is an exponential function of time as described by equations (8) and (12). A similar equation may be written for the  $^{235}U$ - $^{207}Pb$  decay system.

The integrals for the  $^{206}Pb/^{204}Pb$  and  $^{207}Pb/^{204}Pb$  ratios were solved numerically. Values obtained for the core growth constant  $\varepsilon$  for core-mantle Pb partition coefficients of 5, 3, and 2 are 8.5, 5.4, and  $3.5 \times 10^{-9} \text{ yr}^{-1}$ , respectively. For a partition coefficient value as low as 1,  $\varepsilon$  cannot be computed. Figure 3a shows the growth of the core with time for the three partition coefficient values and in Fig. 3b is plotted the growth of  $\mu_t^m$  for the same values. The calculated present-day  $\mu$  value for average crust-mantle is about 9.5 and is almost independent of the distribution coefficient and growth constant. The  $\mu$  value for the bulk Earth is, however, above all determined by the Pb distribution coefficient ( $\mu^{Earth} = 1.38 \pm 0.05$ ,  $3.0 \pm 0.1$ ,  $4.4 \pm 0.1$  for  $D_{Pb}^{c/m} = 5, 3, 2$ , respectively). This model is compatible with hot accretion which left the Earth completely or partially molten and enabled metallic droplets to sink towards the centre and form a continuously growing core.

## Discussion and conclusions

Pb isotope data are probably only compatible with homogeneous accretion of the Earth. Simple models corresponding to the two extreme homogeneous accretion hypotheses of (1) relatively cool accretion with subsequent heating by radioactive decay and (2) hot accretion, show that core formation was probably not quasi-simultaneous with accretion, as is widely held, but occurred after or during a period of several hundred Myr following accretion. The exact definition of the time of core formation,  $t_c$ , in model 1 and mass of core,  $\beta_c$ , in model 2, is ultimately dependent on and determined by the rate of Pb exchange between metallic and silicate phases at the pressures and temperatures prevalent for each point in the protomantle. If Pb exchange with the surrounding silicate phase is negligibly small when segregated metallic bodies reach, for example, metre scale, then this is the time measured by  $t_c$  (model 1); subsequent growth to larger units and shifts in their relative position to the centre of the Earth will not be measured. Therefore  $t_c$  will be a maximum time for the actual core formation. Similarly, in model 2 all (in this example) metre-sized or

**Fig. 3** Model 2: *a*, growth of relative mass of core,  $\beta_t$ , with time for three values of the core growth constant  $\epsilon$  obtained for core-mantle partition coefficients of 5, 3, and 2. *b*, Change of the mantle  $\mu$  value with time for  $D_{Pb}^{c/m} = 5, 3$ , and 2. The bulk Earth  $\mu$  value if primarily dependent on the core-mantle Pb partition coefficient.

larger metallic bodies would be included in the quantity  $\beta_t$ , regardless of whether they were uniformly distributed within the protomantle, or formed a layer, or were part of the actual core.

The shortcomings of both these simple models are severe: for example, energy released during core formation and cooling only on the surface of the Earth will cause non-uniform and time-variant temperature distribution, only the latter is taken into account in model 1, though not in model 2. Non-uniform temperature distribution will mean that partial segregation of the metallic phase may occur in some parts of the Earth earlier than in others. Then the calculated time of core formation in model 1 will become an average value. In model 2 this will cause the rate of core growth  $\epsilon$  to be variable in time. Therefore both models are oversimplifications which may only serve to demonstrate that there was probably a minimum time interval of some hundred Myr between accretion and completion of core-formation, but which cannot provide any detailed model of the process; such a model would have to take account of non-uniform temperature distribution.

Model 1 would entail the core being in equilibrium with the mantle for all non-radiogenic elements; from model 2 it would follow that the total core is now in disequilibrium with respect to all elements. This disequilibrium may easily be calculated from equations (2) and (11) and acts in such a way that all elements which partition into the core are depleted in the mantle below their equilibrium abundance and vice versa. It seems, however, that siderophile elements are on the contrary less depleted in the mantle

than demanded by equilibrium considerations<sup>18,19</sup>. This apparently leads to a paradox. Enrichment in the mantle of elements which are expected to partition into the core seems to demonstrate disequilibrium between core and mantle, on the other hand radiogenic Pb suggests that equilibrium between core and mantle had once been reached. Assuming that this disequilibrium is real and not just an indication of our lack of knowledge of distribution coefficients at high pressures and temperatures, a solution might be that temperatures within a considerable part of the Earth have never been sufficient for a metallic phase to separate. After core formation, however, this primordial material must have been thoroughly homogenised with depleted mantle to account for the radiogenic Pb excess. It is not possible to attribute this low temperature, primordial material to a chilled outer surface: a chilled protocrust would be expected to have a low  $\mu$  value and would thus be depleted in  $^{207}\text{Pb}$  for any given  $^{206}\text{Pb}$  value relative to the mantle. On the contrary, the continental crust is enriched in  $^{207}\text{Pb}$ . But Ringwood's model<sup>18</sup> of accretion and core formation would (with the exception of the time of core formation) fit these constraints. The interior of the Earth accretes cool, a metal phase separates only from the hot outer regions and collects into bodies which sink to the centre without attaining equilibrium with the material which they pass through. Subsequently, depleted and undepleted mantle regions were homogenised by convection. The  $^{207}\text{Pb}$  excess in the continental crust may indicate that the major part of the crust was formed from depleted mantle before homogenisation was achieved.

A time interval of some hundred Myr does not invalidate the precipitation hypothesis<sup>20</sup> for the origin of the moon. Although Ringwood states<sup>20</sup> that the moon forms after separation of the Earth's core, there is no reason why this has to be so, as long as the surface temperature on the Earth during the last stages of accretion is sufficiently high to evaporate silicates but not high enough to volatilise iron<sup>18</sup>.

# Neurotransmitter synthesis and uptake by isolated sympathetic neurones in microcultures

L. F. Reichardt & P. H. Patterson

Harvard Medical School, Department of Neurobiology, 25 Shattuck Street, Boston, Massachusetts 02115

*Assays of isolated single sympathetic neurones show that their transmitter functions can be either adrenergic or cholinergic depending on growth conditions. The data suggest that the number of transmitters made by most mature individual neurones is restricted.*

DEVELOPMENT of transmitter functions by primary sympathetic neurones cultured *in vitro* is remarkably plastic<sup>1-3</sup>. When grown alone in certain conditions, rat sympathetic neurones become primarily adrenergic. They develop the functions necessary for synthesis, uptake, storage, and release of catecholamines, but show relatively low levels of cholinergic function<sup>4-6</sup>. These

neurones can form morphological synapses on each other which contain high concentrations of small granular vesicles<sup>7-9</sup> but show no physiological activity, probably because the neurones are not very sensitive to catecholamines<sup>10</sup>. Cultures of these same neurones, grown with large numbers of non-neuronal cells, however, develop many cholinergic properties. They synthesise acetylcholine (ACh) and form functional cholinergic synapses with each other, heart, and skeletal muscle<sup>1-3, 11-15</sup>.

Medium 'conditioned' by incubation for 2 d with appropriate non-neuronal rat cells can also induce ACh synthesis and cholinergic synapse formation<sup>5, 9, 16, 17</sup>. The extent of ACh synthesis and cholinergic synapse formation increases as the neurones are exposed to higher concentrations of conditioned medium<sup>9, 16, 17</sup>. In contrast, development of the functions necessary for catecholamine synthesis and accumulation is repressed in a dose-dependent fashion by increasing concentrations of conditioned medium<sup>16</sup>. Among the neurones that establish themselves in culture there is little cell death and different doses of conditioned medium do not significantly change the number of neurones that survive<sup>16, 18</sup>. Therefore, it seems likely that a single population of immature sympathetic neurones is able to differentiate in more than one direction. By examining single cells, we hoped to determine how the development of transmitter function is regulated in individual neurones. In particular, is the population shifted from primarily single adrenergic neurones to primarily single cholinergic neurones by growth in high concentrations of conditioned medium? In the intermediate conditions do most single neurones simultaneously express both cholinergic and adrenergic functions? Our biochemical studies on these questions have been reported in preliminary form<sup>19</sup>. Motivated by similar objectives, Furshpan *et al.*<sup>12</sup> and Landis<sup>8</sup> have recently made physiological and morphological observations on individual neurones grown in conditions similar to ours.

### Synthesis of transmitter

When primary sympathetic neurones were plated at low density into micro-wells grown in conditioned medium lacking the cholinergic 'factor', and examined after 4 weeks, many wells were found to lack neurones. Others contained one visible neurone (Fig. 1), while still others contained 2-20 neurones. If only single neurones were plated initially, a Poisson distribution of neurones per well could be anticipated. In fact, small clusters of neurones were also plated so a typical plate contained 35 empty wells, 2-5 wells with single neurones, and 20 wells with more than one neurone.

**Fig. 1** An isolated sympathetic neurone. This montage shows an isolated neurone, grown on a dried collagen drop, with its neuritic ramifications. To assay transmitter synthesis the neurones were grown in Falcon 3034 Terasaki culture plates. One of these plates contains 60 wells with a capacity of 10  $\mu$ l each. Approximately 50  $\mu$ g of rat tail collagen in 10  $\mu$ l 0.1% acetic acid<sup>20</sup> was evaporated in each well. The plates were then sterilised under an ultraviolet lamp. Sympathetic neurones were dissociated from newborn rats (Charles River CD)<sup>4, 21</sup>. In some experiments, these were plated at appropriate dilutions directly into the micro-wells and allowed to settle for 2 h before conditioned medium (CM) or control L-15 CO<sub>2</sub> medium with methocel, rat serum, and nerve growth factor flooded the wells<sup>4, 16</sup>. In other experiments, cardiac cells were dissociated from the hearts of newborn rats with collagenase (EC 4.24.3) (Worthington type I, 1 mg ml<sup>-1</sup> in Ca<sup>2+</sup>, Mg<sup>2+</sup>-free Hanks solution for 20 min at 37 °C) and approximately 500 cells were seeded in each well. After 2 h, the wells were flooded with complete L-15 CO<sub>2</sub> medium containing rat serum, but lacking methocel and nerve growth factor. After 1-4 d, the heart cells had formed monolayers in the wells. At this point, the wells were seeded with neurones at an appropriate dilution and incubated with complete L-15 CO<sub>2</sub> medium<sup>4, 16</sup> containing methocel, rat serum and nerve growth factor. In all our cultures, proliferation of heart and other non-neuronal cells was prevented by  $\gamma$ -irradiation (5,000 rad over 25 s) 2 d after the neurones were seeded. Neurones adhering to the sides of these wells were scraped off 2 d after plating with a tapered Teflon rod. Cells were grown for 28-35 d in the same L-15 CO<sub>2</sub> medium, which was changed on day 2 and every 4 d thereafter. The wells were then scanned with the phase contrast optics and only those in which the neurones could be counted easily were used for studies of transmitter synthesis and uptake. In preparation for labelling, the plates were washed twice with complete L-15 CO<sub>2</sub> medium lacking methocel and three times with complete L-15 CO<sub>2</sub> medium lacking methocel, tyrosine, and choline. The neurones were starved for 30 min in this medium and the plates washed three times more with complete L-15 medium lacking methocel, tyrosine and choline. At this point 10  $\mu$ l of this same medium, containing 0.25  $\mu$ g freshly added ascorbate, 700 pmol <sup>3</sup>H-L-tyrosine (10-20 Ci mol<sup>-1</sup>), and 700 pmol <sup>3</sup>H-choline (10.1 Ci mmol<sup>-1</sup>), were added to each well. At 4 and 8 h later, an additional 1  $\mu$ l of the same medium, containing 0.25  $\mu$ g fresh ascorbate, was added to each well. After 12 h incubation at 37 °C, the plates were washed three times more with the same medium, without isotope. The wells were drained, and each well was filled with 10  $\mu$ l of pH 1.9 buffer containing unlabelled standards<sup>4, 22</sup>. The plates were stored for 1-48 h at -20 °C and wells were thawed and frozen twice before the contents were applied to paper, and the transmitters were separated by high voltage electrophoresis (6,000 V, 90 min)<sup>22</sup>. The sections of paper containing dopamine, NA and ACh were identified<sup>22</sup>, cut out, and counted<sup>4</sup>. The counting efficiency (~25%) was determined by drying on paper known quantities of the tritiated precursors. CM containing the 'cholinergic factor' was obtained by incubating 20 ml of complete L-15 CO<sub>2</sub> medium for 2 d with a 75-cm<sup>2</sup> monolayer of the rat glioma cell line C6 (ATCC CCL107<sup>23</sup>) in a Falcon 7004 tissue cultured flask. CM lacking the 'factor' was obtained by incubating the same amount of medium with a monolayer of embryonic chicken heart cells in the same type of flask<sup>16</sup>. The chicken heart cells were obtained from 10-d chicken embryos by collagenase dissociation, using the procedure used for rat hearts. Single neurones are apparently more fastidious than mass neuronal cultures; so that standard culture conditions used in these studies were not always successful. It was particularly difficult to obtain firm adhesion of single neurones to collagen sheets. All manipulations had to be performed very gently, and it was useful to verify that the neurone remained in the well at the end of the many medium changes that followed the incubation with labelled precursors. Since 1 fmol of labelled transmitter provided only 10-20 c.p.m., it was important to clean the electrophoresis tanks before each run and to use standards, blotting paper, scissors, and scintillation fluid that had not been contaminated by other experiments. With these precautions, the background was reduced to approximately 30 c.p.m. in favourable experiments. Unknown causes gave higher backgrounds in some experiments and these results were discarded. All vials were counted twice for 10 min and the results were averaged. The pieces of paper containing transmitters were compared to equal sized paper pieces, cut just in front and behind the transmitter spots.

Most of these wells were incubated with <sup>3</sup>H-tyrosine and <sup>3</sup>H-choline for 12 h and synthesis of <sup>3</sup>H-ACh and <sup>3</sup>H-noradrenaline (NA) was measured after the incubation. The results of a typical experiment are presented in Fig. 2. Significant amounts of <sup>3</sup>H-ACh were not detected in any well. Synthesis of <sup>3</sup>H-NA was not detected in any wells lacking visible neurones. In the 10 wells containing a single neurone, however, 10-50 fmol of NA synthesis was seen. Wells containing more neurones made, on the average, more <sup>3</sup>H-NA. (Only the results from the wells containing 0, 1 and 4 and 5 neurones are presented in Fig. 2 because the other classes provided no additional insight.) These results show that single neurones

Fig. 2  $^3\text{H}$ -ACh and  $^3\text{H}$ -NA synthesis by neurones grown in control medium. The neurones were grown for 29 d in complete L-15  $\text{CO}_2$  medium supplemented with 20% of the same medium first conditioned on a monolayer of chicken embryo heart cells. The neurones in each well were counted and incubated with  $^3\text{H}$ -choline and  $^3\text{H}$ -tyrosine. The results are plotted in separate graphs for those wells containing: a, 0; b, 1, or c, 4 or 5 neurones. No synthesis of detectable  $^3\text{H}$ -ACh was seen in any well. The amount of  $^3\text{H}$ -NA synthesised rounded to the nearest multiple of 10 fmol, is plotted on the abscissa. The number of wells making a particular amount of  $^3\text{H}$ -NA is plotted on the ordinate.

make detectable quantities of  $^3\text{H}$ -NA, but not  $^3\text{H}$ -ACh, when grown in these conditions. Every neurone synthesised and accumulated detectable transmitter, but the amount made by a single cell may differ by at least a factor of 5.

Why do single neurones make such differing quantities of  $^3\text{H}$ -NA? To see whether differences in transmitter synthesis simply reflected differences in metabolic activity of neurones, we measured the acid precipitable radioactivity in  $^3\text{H}$ -tyrosine and  $^3\text{H}$ -choline derivatives. The results are shown in Fig. 3. There is a correlation, but not a strong one between the amounts of radioactivity in the acid precipitable and NA fractions. Some neurones were metabolically active, but produced relatively little transmitter. By this criterion, the neurones seem to have differentiated to different extents after culture for 4 weeks *in vitro*. Immature neurones have been seen in superior cervical ganglia as late as 3 weeks after birth<sup>24</sup>. Our results could reflect this documented *in vivo* heterogeneity, but alternatively, may reflect limitations in our methods for nerve culture.

The primary sympathetic neurones can also be grown in conditions which promote cholinergic development. Figure 4 shows the results of one representative experiment in which the neurones were plated onto monolayers of rat embryo heart cells and labelled 32 d later with  $^3\text{H}$ -tyrosine and  $^3\text{H}$ -choline. Wells containing heart cells but not neurones made neither  $^3\text{H}$ -NA nor  $^3\text{H}$ -ACh. In the wells containing neurones, the average synthesis of  $^3\text{H}$ -ACh was seven times that of  $^3\text{H}$ -NA, but single neurones did not synthesise both transmitters in this ratio. In 26 of the 30 wells that seemed to contain a single neurone we detected synthesis of

8–53 fmol of  $^3\text{H}$ -ACh without detectable  $^3\text{H}$ -NA synthesis. In three wells there was synthesis of 9–17 fmol of  $^3\text{H}$ -NA but no detectable  $^3\text{H}$ -ACh. In only one single neurone well was there synthesis of both  $^3\text{H}$ -ACh and  $^3\text{H}$ -NA, 6 fmol and 3 fmol respectively. The results suggest that there are at least two and possibly three classes of neurones, differing in their patterns of transmitter synthesis. Support for this interpretation is provided by the data obtained from wells containing more than one neurone. Synthesis of  $^3\text{H}$ -ACh was seen in all five wells containing two neurones, but  $^3\text{H}$ -NA was seen in only one, suggesting that four wells contained two cholinergic neurones while one well may have contained one adrenergic and one cholinergic neurone. In the wells containing more neurones, highly disparate ratios of  $^3\text{H}$ -ACh to  $^3\text{H}$ -NA synthesis were seen. These fluctuations also suggest that more than one class of neurones developed in these wells.

Several experiments have been done on single cells grown in conditions where the average ratio of  $^3\text{H}$ -NA synthesis is closer to one. In these experiments, the neurones developed in the presence of L-15  $\text{CO}_2$  medium conditioned by previous growth with the rat glioma cell line C6. Neuronal mass culture grown in this medium make significant amounts of  $^3\text{H}$ -ACh<sup>16</sup>. The results with the single neurones are summarised in Table 1. In 50% conditioned medium approximately 45% of the neurones made detectable levels of  $^3\text{H}$ -ACh, but not  $^3\text{H}$ -NA; roughly the same percentage made  $^3\text{H}$ -NA, but not  $^3\text{H}$ -ACh. In about 5% of the wells synthesis of both transmitters was seen. In 20% conditioned medium, 90% of the neurones were adrenergic; the remainder were cholinergic. The

Fig. 3 Incorporation of radioactivity into the acid-precipitable and NA fractions of single neurones. The cells from Fig. 1 were used for this experiment. After high voltage electrophoresis, strips of paper including the regions within 1 cm of the origin were placed on a Millipore filter with the sides to which radioactivity had been applied uppermost. These strips were washed with cold 10% trichloroacetic acid, and counted in a scintillation counter to determine the amount of acid precipitable radioactivity. The background from five wells containing no neurones averaged 42 c.p.m. and was subtracted. c.p.m. acid precipitable radioactivity is plotted on the ordinate; fmol  $^3\text{H}$ -NA in the precipitate on the abscissa.

Table 1 Transmitter synthesis by single neurones grown in various conditions

Growth conditions	ACh neurones (a)	NA neurones (b)	ACh and NA neurones (c)	Negative neurones (d)	ACh:NA ratio
Control	0	18	0	0	<0.02
20% CM	2	21	0	0	0.15
50% CM	15	15	2	2	2.4
Heart cells	26	3	1	0	7.0

Pooled results are given of all experiments on neurones grown in control medium, in 20% and 50% conditioned medium (CM), and on rat heart monolayers. Procedures for growing neurones in control medium and on rat heart monolayers were as described in Figs 1 and 3. Neurones grown with 20% or 50% conditioned medium (conditioned with C6 cells) were labelled 25–28 d after plating. The values are the numbers of single neurones making only ACh (a), the number making only NA (b), the number making ACh and NA (c), the number making neither transmitter (d), and the average ratio of ACh to NA synthesis in the pooled results, including wells with more than one neurone.

**Fig. 4**  $^3\text{H}$ -ACh and  $^3\text{H}$ -NA synthesis by neurones grown on heart cells. Culture age was 32 d. The neurones in each well were first counted, then the wells were washed and incubated with  $^3\text{H}$ -choline and  $^3\text{H}$ -NA (see Fig. 1 legend). The results are summarised in separate graphs for wells containing 0 (c), 1 (b), or 2 (a) neurones. The fmol  $^3\text{H}$ -ACh synthesised by a particular well is plotted on the abscissa. The number of wells in which there was a particular amount of  $^3\text{H}$ -ACh synthesis is plotted on the ordinate. Values for  $^3\text{H}$ -ACh synthesis are rounded to the nearest multiple of 10 fmol. (There were no examples, though, in which 2–5 fmol  $^3\text{H}$ -ACh was synthesised, and only one example in which a cholinergic neurone made less than 8 fmol  $^3\text{H}$ -ACh. That neurone seemed to make 6 fmol  $^3\text{H}$ -ACh and 3 fmol  $^3\text{H}$ -NA). When there was detectable  $^3\text{H}$ -NA synthesis in a well, the amount has been written directly above or to the right of the appropriate bar. Averaged,  $^3\text{H}$ -ACh synthesis by all these neurones was seven times as high as  $^3\text{H}$ -NA synthesis.

pooled results of all our experiments are summarised in Table 1. It seems that most cells become primarily cholinergic or adrenergic, but that the percentage committed to either path depends on the growth conditions.

### Uptake of noradrenaline

Transmitter synthesis is only one parameter of neuronal function. Many neurones also have high affinity uptake systems for the transmitters that they synthesise, store, and release (compare ref. 25). We have found that sympathetic neurones cultured in conditions which promote adrenergic development possess such an uptake system for NA, with a  $K_m$  of  $\sim 1 \mu\text{M}$ , which is blocked by cocaine. Storage of this NA is abolished by reserpine<sup>5</sup>. Mass cultures of sympathetic neurones grown on monolayers of rat heart retained the ability to concentrate and store  $^3\text{H}$ -NA, but at a reduced rate (data not shown). One possibility was that no  $^3\text{H}$ -NA uptake occurred in neurones making ACh.

To see whether cholinergic neurones could also concentrate and store NA, single neurones were grown on rat heart monolayers for 30 d and were then labelled with  $^3\text{H}$ -choline, and  $^3\text{H}$ -NA (50 nM). The results are presented in Fig. 5. Wells containing no neurones neither made  $^3\text{H}$ -ACh nor concentrated  $^3\text{H}$ -NA. Significant  $^3\text{H}$ -NA uptake was seen in all 57 wells containing a single neurone;  $^3\text{H}$ -ACh synthesis was seen in 53 of these same wells. Clearly, most neurones have an uptake system for NA. The few that did not do both may have been cells, like those in Fig. 4, that synthesised only  $^3\text{H}$ -NA and not  $^3\text{H}$ -ACh.

### Conclusion

Examination of transmitter synthesis and uptake functions in developing sympathetic neurones has revealed the existence of two or three different classes of cells. The first class, virtually the only

class present when the neurones are grown alone, is adrenergic. The individual neurones synthesise considerable NA, but no detectable ACh. In mass culture, they have a high affinity uptake system for NA<sup>5,6</sup>. They almost certainly correspond to the neurones described by Furshpan *et al.* and Landis<sup>1,2,8</sup> that, when stimulated, evoked only adrenergic responses in heart cells and have varicosities filled with small granular vesicles after  $\text{KMnO}_4$  fixation to localise endogenous NA.

The second class synthesises considerable amounts of ACh, but no detectable NA; however, these neurones retain the ability to concentrate and store exogenous NA (Fig. 5). These probably correspond to the neurones described by Furshpan *et al.*<sup>12</sup> and Landis<sup>8</sup> which contained no endogenous small granular vesicles, formed cholinergic synapses on themselves and evoked cholinergic but not adrenergic responses in heart muscle cells.

Furshpan *et al.*<sup>12</sup> and Landis<sup>8</sup> have also presented convincing evidence for the presence in young cultures of a third class of neurones that releases both cholinergic and adrenergic transmitters on heart muscle cells. Their experiments did not show that single cells synthesised both transmitters; conceivably they could have concentrated NA made by other neurones on the dish. They also did not show whether the neurones were transiently or permanently bifunctional. It is possible that all young neurones responding to the cholinergic inducer substance(s) might pass through a bifunctional phase. Our experiments with more mature neurones do not contribute to the study of these very interesting cells. Although we have found occasional neurones that seemed to synthesise both NA and ACh (Fig. 4, Table 1), they were rare enough to be possible artefacts. Either a hidden neurone or terminals from one whose cell body had been lost might explain our results. Neuronal numbers can be counted with high, but not absolute, reliability with phase contrast optics. This limitation in our methods makes it difficult to study rare classes of neurones. In the future, of course, neurones shown electrophysiologically to be releasing both ACh and NA can also be assayed for ACh and NA synthesis from labelled precursors.

The two major classes, those neurones exhibiting cholinergic and adrenergic biosynthetic activities, are present in different proportions in different growth conditions. In our experiments, the fraction of neurones committed to ACh synthesis increased as the ratio of ACh to NA synthesis in the whole population increased (Table 1). In addition to the shift in the population of neurones caused by conditioned medium or heart cells, it is also possible that these 'cholinergic' factor(s) when present in higher concentrations,

**Fig. 5**  $^3\text{H}$ -NA uptake and  $^3\text{H}$ -ACh synthesis by the same neurones. Neurones were grown for 30 d in complete L-15  $\text{CO}_2$  on monolayers of embryonic rat heart cells. The neurones in each well were counted. Then they were incubated with  $^3\text{H}$ -choline and unlabelled tyrosine for 10 h. Each well then received  $2 \mu\text{l}$  of the same medium containing 50 fmol  $^3\text{H}$ -NA (22 Ci  $\text{mmol}^{-1}$ ; NEN). The final  $^3\text{H}$ -NA concentration was 50 nM. Wells were washed and cells collected 2 h later. The results are for wells containing 0 (b) or 1 (a) neurone. The fmol  $^3\text{H}$ -ACh synthesised is on the abscissa; the fmol  $^3\text{H}$ -NA uptake is on the ordinate. Each circle represents a single well.

might cause neurones committed to the cholinergic decision to produce higher levels of ACh. The heterogeneity in the individual neuronal responses in our experiments precluded a firm answer on this point.

Virtually every single neurone that survived made at least one transmitter in our experiments. This result suggests that there are no large populations of 'silent' neurones making neither ACh nor NA in mass cultures grown in adrenergic or cholinergic conditions. Since the same number of neurones survive in cultures grown in several different concentrations of cholinergic 'factor'<sup>16</sup>, selective death of adrenergic cells in cholinergic conditions and the reverse are unlikely to explain the alterations in transmitter synthesis. Instead, individual neurones probably retain developmental plasticity at the time they are plated on the dish.

Most primary sympathetic neurones did not make detectable amounts of ACh and/or NA (Figs 2,4; Table 1), suggesting that regulatory mechanisms limit transmitter synthesis by single sympathetic neurones. Such mechanisms may force individual cells to respond in a 'flip-flop' fashion to the cholinergic 'factor'. The young dual functional neurones described by Furshpan *et al.*<sup>12</sup> may have been in a transitional state when they were examined. This may also have been true for the few neurones that we observed which made two transmitters. The heterogeneity in response of the individual neurones to a given level of the cholinergic 'factor' may reflect the heterogeneity in developmental time course that has been documented *in vivo*<sup>24</sup>, or it could reflect microheterogeneity in the tissue culture environment. Either could explain the broad distribution in rate of transmitter synthesis by single neurones.

In some cells, however, regulation of transmitter synthesis is more complex than predicted by the 'flip-flop' model. In several systems there is evidence for the simultaneous presence of more than one transmitter in a single neurone<sup>26</sup>. Neuroblastoma clones have been isolated which contain high levels of tyrosine hydroxylase and choline acetyltransferase<sup>27</sup>. Similarly, the rat pheochromocytoma PC12 synthesises both NA and ACh<sup>28-30</sup>. Some, but not all sub-clones of PC12, retain high levels of both tyrosine hydroxylase and choline acetyltransferase. While single cell analysis has not been done on this clonal line, the available results make it unlikely that cell lines are forced to respond in a 'flip-flop' fashion. Possibly, the clonal lines are frozen in an embryonic state of development. Alternatively, choices between transmitters are not obligatory, but are highly probable in the conditions in which the cultured sympathetic neurones develop.

The uptake of NA by neurones that synthesise ACh is consistent with the observation that NA can be concentrated into small granular vesicles of identified single neurones that secrete ACh<sup>8</sup>. Experiments on mass cultures had indicated that NA uptake was reduced 10-20-fold in cholinergic growth conditions (data not shown), so we had expected NA uptake to be restricted to adrenergic cells. Possibly the proteins required for the uptake and storage of NA are regulated independently of the NA biosynthetic

enzymes. Indeed, neuroblastoma clones that have one, but not another of the biosynthetic enzymes for NA have been described<sup>31</sup>, suggesting that every adrenergic function can be independently regulated. Alternatively, all the sympathetic neurones may develop some adrenergic functions before they respond to the cholinergic 'factor'. In support of this interpretation, sympathetic cells in newborn rats are known to be weakly fluorescent<sup>24</sup> and to initially form *in vitro* endings with high concentrations of small granular vesicles which are lost with cholinergic development<sup>3</sup>. At least one sympathetic neurone-like rat pheochromocytoma clone also synthesises significant amounts of NA in the 'undifferentiated' state<sup>28</sup>. Possibly, then, the proteins required for synthesis, uptake, storage, and release of NA are made in most young sympathetic neurones. Their synthesis is reduced or eliminated by contact with the cholinergic 'factor', but the activities which are more stable persist in lower amounts in the developing cholinergic cell.

We thank Drs Linda Chun, Philippa Claude, Edwin Furshpan, and David Potter for suggestions and for reagents, and Karen Fischer and Doreen McDowell for their aid in maintaining cultures. ## Detection of acceptor sites on human lymphocytes for antigen-specific T cell factors

M. J. Taussig\* & A. P. Finch†

Basel Institute for Immunology, Grenzacherstrasse 487, Postfach, 4005 Basel 5, Switzerland

*Mouse antigen-specific T cell factors are absorbed by human peripheral blood lymphocytes at acceptor sites. The acceptors are products of HLA-linked genes, which may be human immune response genes.*

\*Present address: Department of Immunology, ARC Institute of Animal Physiology, Babraham, Cambridge, UK.

†Present address: Department of Immunology, Trinity College, Dublin, Eire.

THE immune response or Ir genes control the levels of immune responses to specific antigens. In many species, an important group of such genes has been shown to lie in the major histocompatibility complex (MHC) (ref. 1). Considerable interest attaches to the Ir genes of man, in particular because of the associations between antigens of the HLA system (the human MHC) and certain diseases, many of an autoimmune character, such as ankylosing spondylitis, Addison's disease, juvenile diabetes, coeliac disease and multiple sclerosis<sup>2,3</sup>. Ir gene polymorphism is

thought to play an important part in these disease associations. Some progress has been made in demonstrating human Ir genes, particularly in certain allergies<sup>4-6</sup>, but a major obstacle in experimental work is the ethical and practical problem of immunising volunteers and their families with antigens of scientific interest. In order to avoid these difficulties, we have attempted to detect products of Ir genes on human lymphocytes *in vitro*, using methods which have been successful in the mouse. In particular we have looked for Ir gene products involved in immunological cell interactions. Two types of such products have been described recently, namely the antigen-specific T cell factors, which are soluble mediators of T cell-B cell<sup>7</sup> and T cell-T cell<sup>8</sup> interaction, and the cell-bound acceptors, the sites on the lymphocyte surface where reaction with the T cell factors takes place<sup>7</sup>. The factors include antigen-specific helper and suppressor products which are assayed by their abilities to replace the helper or suppressor effects of T cells *in vivo* or *in vitro*<sup>9-12</sup>, while the acceptors are defined by the capacity of lymphocytes to absorb the specific factors<sup>7</sup>. In the mouse, both the factors and the acceptors are coded at least partially by genes in the I region of the H-2 complex<sup>7,13,14</sup>, and it has been proposed that they are the structural products of the Ir genes which are found in the same region. Thus, the inherited absence of either the helper factor for a particular antigen or its acceptor, is associated with low response to that antigen in mice<sup>7</sup>. In this report we describe a remarkable feature of the mouse specific helper factors, namely their ability to be absorbed by human peripheral blood lymphocytes (PBL). On interaction with the mouse factor, human PBL are activated and proceed to antibody production *in vitro*<sup>15</sup>. This suggests that critical mechanisms for the interaction between helper and acceptor structures have been preserved in speciation. Furthermore, the acceptor sites of human PBL seem to be polymorphic: for antigens such as synthetic polypeptides under murine Ir gene control, lymphocytes of different human individuals can be shown to be either high or low absorbers of the relevant T cell factors. Family analyses indicate that the acceptor genes are linked to the HLA complex, and preliminary mapping of two loci has been achieved in HLA-recombinant families. These findings provide an approach to the detection and mapping of the Ir genes of man.

### T-cell factor interaction with human lymphocytes

Antigen-specific T cell helper factors were prepared against sheep erythrocytes (SRBC) and the synthetic polypeptides (T,G)-A-L (batch 1383) and (Phe,G)-A-L (batch 223). The method, detailed elsewhere<sup>7,9</sup>, involved *in vitro* incubation of specifically educated (primed) mouse (C57B1/6) thymocytes together with antigen for 6-8 h. The cell-free supernatants of the educated T-cell cultures were the source of T-cell factors. Factor activity was assayed, before and after absorption by human lymphocytes by transfer into irradiated (700 rad) syngeneic mouse recipients together with bone marrow cells and antigen<sup>7,9</sup>. Plaque forming cells (PFC) against the relevant antigen were measured 8-10 d later for SRBC or 12-14 d later for polypeptides, in the spleens of the animals, using appropriately coated erythrocytes<sup>9</sup> and compared with suitable controls. Donors of human lymphocytes were employees of Hoffman-La Roche, Basel, and members of their families. Samples of 20 ml of blood were taken in heparin and lymphocytes separated by Ficoll sedimentation<sup>16</sup>. The cells were washed three times in medium free of calcium and magnesium and maintained before use in phosphate buffered saline (PBS) containing 10% foetal calf serum. For absorption of T-cell factor, 10<sup>7</sup> PBL from each donor were sedimented and resuspended in 2-3 spleen equivalents of T-cell factor (approximately 0.5 ml of the supernatant of educated T-cell culture), without further addition of antigen. After incubation for 30 min in ice, the lymphocytes were removed by centrifugation and the absorbed supernatants were mixed with mouse bone marrow cells and antigen and transferred into irradiated recipients (five per group) as described above. All the absorption tests on human lymphocytes were carried out strictly blind, with the identity or HLA type of individuals concerned being revealed only after final results had been obtained. HLA-typing was by standard techniques, using the facilities of the Basel Institute for Immunology.

**Table 1** PFC responses before and after absorption of specific mouse T cell factors with lymphocytes of different human donors

PBL donor (initials)	Mouse factor specific for		SRBC
	(T,G)-A-L	(Phe,G)-A-L	
-(Controls)	2,100 ± 280	3,600 ± 312	4,400 ± 360

\*High absorber.

†Low absorber.

Incubation of the antigen-specific mouse helper factors with human PBL results, in many cases, in the complete removal of factor activity from the supernatant. This phenomenon is consistently observed in randomly-selected human donors for the helper factor specific for SRBC. Table 1 shows a typical absorption result, in which 10<sup>7</sup> PBL of four donors all removed the SRBC-specific factor. No failure to absorb this factor has yet been observed. But, when the mouse factors specific for the synthetic polypeptides (T,G)-A-L and (Phe,G)-A-L were used, the PBL of some but not all donors were found to absorb. In the majority of cases, clear-cut distinction between high and low absorbers was possible. Table 1 illustrates this—PBL of donors GE and HB absorbed the (T,G)-A-L specific factor, whereas those of GM and RF failed to remove the factor. A similar result is seen for the (Phe,G)-A-L factor, where this time GE and GM are high absorbers, and HB and RF are low absorbers. It thus seems that acceptor sites for the (T,G)-A-L and (Phe,G)-A-L specific factors are expressed on the PBL of some but not all individuals, while the ability to absorb SRBC-specific factor has been found on PBL of all individuals so far tested. Moreover, as Table 1 shows, all combinations of high and low absorption seem to be possible in different individuals (with the exception of low to SRBC factor).

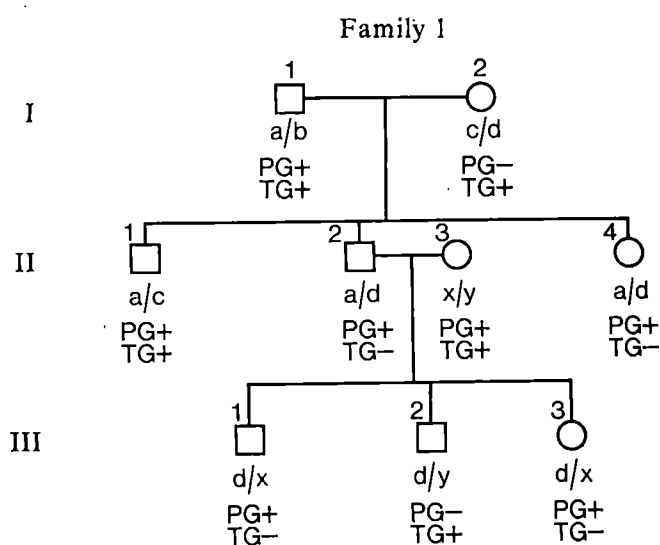

These findings have so far been extended to 41 random individuals, and the results are summarised in Table 2. Approximately 34% of the individuals tested are low absorbers of the (T,G)-A-L factor, 27% are low absorbers of the (Phe,G)-A-L factor, and 15% are low absorbers for both, although it should be noted that a smaller number of donors have so far been tested for (Phe,G)-A-L (26 tested) than for (T,G)-A-L (41 tested). These findings closely resemble those made in the mouse, where the B cells of some low responder strains fail to absorb the (T,G)-A-L or (Phe,G)-A-L specific factors and various combinations of the low absorption phenotypes for the different factors have been found. Note that in the mouse, lack of the acceptor site for an antigen-specific T cell factor can be correlated with low response of the animal to the antigen<sup>7</sup>. The absorption characteristic of each individual was a stable trait which could be detected very reproducibly, as indicated by perfect concordance in a re-test of 25 donors carried out blind, 6 months after first testing.

Family analysis strongly suggests that the abilities to absorb the T-cell factors for the two synthetic polypeptides are indeed inherited as simple Mendelian traits. A typical pedigree in three generations is shown in Fig. 1. This family illustrates the dominance of the high absorption characteristic. For example, the

**Table 2** Absorption of specific mouse T cell factors by human lymphocytes: summary of phenotypes observed

**Fig. 1** Pedigree of abilities to absorb mouse T cell factors. PG+ and PG-, respectively the high and low absorption phenotypes for the (Phe,G)-A-L-specific mouse T cell factor. TG+ and TG-, respectively the high and low absorption phenotypes for the (T,G)-A-L-specific mouse T-cell factor. a, b, c, d, x and y, represent the HLA HLA haplotypes of the family members. *p* and *t*, the genetic loci controlling respectively the absorption of the (Phe,G)-A-L and (T,G)-A-L factors. With respect to the *p* and *t* loci, the signs + and - denote high and low absorption alleles respectively. The key shows the deduced linkage phase of *p* and *t* with each haplotype.

mating II.2 × II.3 between two PG+ individuals gives both PG+ and PG- offspring; this can be interpreted as an intercross between two heterozygotes of genotype  $p^+/p^-$ , in which the 'high absorber' gene  $p^+$  behaves as dominant over its  $p^-$  allele. A similar interpretation applies to the inheritance of the TG character in the offspring of the mating I.1 × I.2. Thus, family data support a model in which the absorption abilities are controlled by two loci (*t*, *p*) each with two alleles ( $t^+$ ,  $t^-$ ;  $p^+$ ,  $p^-$ ), high being dominant over low. Accepting this model and assuming that the population presented in Table 2 is at Hardy-Weinberg equilibrium, the gene frequencies are:  $t^+ \approx 0.4$ ,  $t^- \approx 0.6$ ;  $p^+ \approx 0.5$ ,  $p^- \approx 0.5$ .

### Acceptor relationship to HLA system

On the basis of the situation in the mouse it was obvious to look for a linkage with the HLA region, and indeed inspection of the family in Fig. 1 shows that the genes controlling the TG and PG phenotypes, assigned independently of any knowledge of the HLA typing, segregate with the HLA haplotypes. So far, no cross-over between HLA and the acceptor loci has been observed in over 20 potentially informative offspring of backcross type matings, (other than in families with known recombinations within the HLA complex as described below). Thus, close linkage between the acceptor loci *t* and *p*, and HLA is indicated, though a significant recombination fraction cannot be excluded. In this and other

families several other genetic markers were studied, either with no information (Kk, Kp, Js, Wr<sup>a</sup>, ADA, AK, Inv) or with evidence of independent segregation (ABO, MNSs, P, Rh, Fy, Lu, Kl, Le, Xg<sup>a</sup>, Hp, ACP<sub>1</sub>, PGM<sub>1</sub>, GPT, Gc, Pt and Gm).

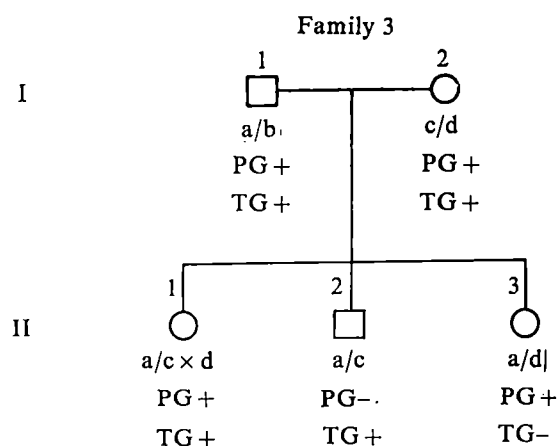

Confirmation that there are indeed two acceptor loci in the HLA complex comes from HLA-recombinant families, one of which is shown in Fig. 2. The recombinational event occurred between the HLA-A and HLA-C loci in the mother and the recombinant haplotype (denoted c × d) is carried by a daughter (II.1). This pedigree shows that crossing over must also have occurred between the acceptor loci *t* and *p*, and that the acceptor locus *t* must be on the HLA-A side of the cross-over event, while the acceptor locus *p* is on the HLA-C side. Figure 3 illustrates this in skeleton form. Further recombinant families are being studied to localise the acceptor genes further.

In some instances, for HLA antigens of the A, B, C series a trait under study is associated with a given marker at another locus of the HLA region, that is, the two traits are in linkage disequilibrium<sup>17</sup>. Analysis of over 40 individuals rules out such a possibility for the TG and PG phenotypes in regard to HLA (ABC), even with the two frequent supertypic specificities w4 and w6, which split the HLA-B antigens into two main groups<sup>18</sup>. It could be more informative to study the associations with the D polymorphism (mixed leukocyte reaction) and Da (D-locus associated) antigens, which are the equivalent of Ia antigens in the mouse.

### Discussion

Our results show that human peripheral blood lymphocytes carry acceptor sites for the mouse T cell factors for the synthetic polypeptides (T,G)-A-L and (Phe,G)-A-L. The abilities of being a 'high absorber' or a 'low absorber' are individual stable characters, which are inherited as simple Mendelian traits linked to the HLA

**Fig. 2** Absorption of mouse T-cell factors in a pedigree containing a recombination in the HLA complex. Abbreviations as in Fig. 1. a, b, c, and d represent the HLA haplotypes of the family members, c × d being the recombinant haplotype.

complex. This situation closely resembles that found in the mouse, where acceptor genes have been demonstrated in the I-region of H-2 and are good candidates for the Ir genes of that species. We therefore propose as a working hypothesis that the acceptor sites detected on human lymphocytes by these methods are products of the Ir genes of man and that high and low absorptions are equivalent to high or low immune responsiveness. To support this proposition, we must test the responsiveness of each individual to the antigen in question. Culture conditions have recently been established for the development of antibody responses by human lymphocytes, in which human PBL are stimulated with antigen and mouse T cell factor *in vitro*<sup>14,15</sup>. Thus, the correlation of factor absorption with responsiveness can now be tested.

The results described with HLA-recombinant families indicate the existence of at least two acceptor loci separable by crossing over. In the mouse, the acceptors are I-region products and carry the Ia antigenic determinants found predominantly on B lymphocytes<sup>7</sup>. In man, at least two loci in HLA have been shown to code for Ia-like B cell alloantigens, one associated with or identical to the HLA-D locus while the other is associated with the HLA-A locus<sup>19</sup>. A similar situation seems to exist in the Rhesus monkey<sup>20</sup>. There are also two loci determining the antigens stimulating the mixed lymphocyte reaction, another property of Ia antigens, with similar mapping<sup>21,22</sup>. In addition, disease associations suggest that some Ir genes may be closely linked to the HLA-D locus<sup>3</sup>. Therefore, on the basis of the detection of lymphocyte acceptor

sites described here, we propose the existence of two Ir gene loci (or regions) in the HLA complex and suggest that one of these is likely to be associated with HLA-D and the other with HLA-A. Further mapping studies are in progress to test this model. The existence of two Ir gene regions in the HLA complex could provide the basis for a selective advantage of certain haplotypes and hence lead to the linkage disequilibrium which is a feature of the distribution of HLA alleles in the population.

These *in vitro* tests of absorption and response may make it possible to study in detail the human Ir genes, avoiding the problems of *in vivo* immunisations of human volunteers with specific antigens of scientific interest. Moreover, the use of antigens and corresponding T factors of direct medical interest, could lead to assessment of predisposition to the HLA-associated diseases (for example, multiple sclerosis, gluten enteropathy), with a higher efficiency than by the present indirect Ir typing through the HLA (A B C D) markers.

We thank Dr Edna Mozes (Weizmann Institute) for gifts of synthetic peptides.

## letters to nature

### Temporal and spectral variation of Cyg X-1

AMONG galactic X-ray sources, Cyg X-1 is distinctive because of its marked variability. Its X-ray intensity curve exhibits apparently aperiodic variation of large amplitudes<sup>1-3</sup>. It is tempting to suppose that this peculiarity of Cyg X-1 is related to the physical properties of the accretion disk formed around the black hole presumed to accompany the supergiant HDE226868 optically identified with Cyg X-1. We report here certain features of the subsecond variability concluded from a recent rocket observation.

The rocket observation of Cyg X-1 was carried out, using a rocket launched from Kagoshima Space Center, for ~250 s starting at 0502 UT 24 September, 1975 when the source was in the low-state. The total effective area of four Xe-CO<sub>2</sub> filled proportional counters was 680 cm<sup>2</sup>. The counts in every 0.625 ms time bin in three energy bands, nominally 1.5-5, 5-10 and 10-25 keV, hereafter referred to as L, M and H band respectively were telemetered. The counting-rate is corrected

for the small jittering of the rocket attitude.

The observed X-ray intensity profile is shown in Fig. 1 as a histogram of counts per time bin with a bin width of 0.32 s as an example. The intensity decreased by about 20% during the period of observation and in the first half period flare-like variations are more pronounced compared to the second half period.

The hardness ratio or spectral hardness averaged over 1.28 s, defined as the ratio of counting-rates of the ≤ 10 keV (L+M) and > 10 keV (H) bands, is also shown. It is clear that the spectral hardness also fluctuates in a complex manner with weak correlation to intensity variations, if there is any. The spectral variation becomes even more pronounced for shorter integration times of the order of 0.1 s. Correlation among counting-rate profiles of three energy bands corresponding to the spectral variation was investigated. It should be noted that the H-component occasionally fluctuates with characteristic time scales of the order of 0.1-1 s in a different

**Fig. 1** Intensity and spectral time profiles corrected for aspect are shown from the acquisition of the source until the re-entry of the rocket into the atmosphere. Time resolutions for the intensity and spectral hardness ratio are 0.32 s and 1.28 s respectively. In the first half of the observation, the intensity is approximately 20% higher and the flare-like activity is stronger compared to the latter half. The time scale is shown in units of 0.32 s. *a*, 10–25 keV/1.5–10 keV; *b*, 1.5–25 keV.

fashion from the L- and M-components resulting in the spectral variation.

We define the variability coefficient,  $\eta(t_b)$ , as the square root of the variance,  $V(t_b)_{\text{cyg}}$  due to intrinsic variation of the source, normalised to the average intensity,  $x(t_b)_{\text{cyg}}$ , where  $t_b$  is a bin width;

$$\eta(t_b) = \frac{(V(t_b)_{\text{cyg}})^{1/2}}{x(t_b)_{\text{cyg}}} \quad (1)$$

Statistical estimate of  $\eta(t_b)$  is

$$\eta(t_b) = \frac{(V(t_b) - x(t_b))^2}{x(t_b) - y(t_b)} \quad (2)$$

where  $V(t_b)$  is the total variance,  $x(t_b)$  is the average counts per bin and  $y(t_b)$  is the average background counts per bin;  $\eta(t_b)$ , which decreases monotonically with the increase of  $t_b$ , should exhibit a significant slope over a time range corresponding to the characteristic time scale involved in the variability. Figure 2 shows the variability coefficients as a function of the bin width for respective energy bands. The curves indicate the presence of a characteristic time scale from 0.1 to 1 s for all bands and, in addition, a time scale  $\leq 10$  ms for the H band. The 0.1–1 s time scale is also prominent in the autocorrelation function produced for this observation. The autocorrelation function is similar to that for observations already reported<sup>2,4</sup>. The presence of the  $\sim 10$  ms characteristic time scale was also notified by Canizares and Oda<sup>5</sup>.

In addition to the general variability, Cyg X-1 occasionally exhibits sporadic flares or bursts more than twice the average intensity and of the time scale of 1 s or a fraction thereof. The

sporadic flares from 0.1 to 1 s duration in general seem to have internal spectral structures, average spectral hardness being similar to the overall hardness: spectral softening in the flare is suggested.

It was demonstrated by Terrell<sup>6</sup> that the intensity time profile and the autocorrelation function of Cyg X-1 may be reproduced by the superposition of a number of random pulses of basically constant size and decay time in analogy to the shot-noise. The idea is that the variability is caused by the statistical fluctuation of the rate of underlying unit shot. If we take the shot-noise model with impulsive shots of the decay time  $\tau/2$  with the average shot rate  $\lambda \text{ s}^{-1}$ , the  $\eta$  against  $t_b$  curve approaches a constant  $f/(\lambda\tau)^{1/2}$  for  $\tau \leq t_b$  and tends

**Fig. 2** The variability coefficients against integration time for three energy bands are shown. A characteristic time scale of the order of a second or less is indicated. A  $\leq 10$  ms time scale is noted for the H-band. ●, h (1.5–5 keV); ▲, M (5–10 keV); XH (10–25 keV).

to decrease asymptotically as  $f/(\lambda t_b)^{1/2}$  for  $\tau \leq t_b$  where  $f$  is the fraction of the shot-noise component. Thus, from Fig. 2 we estimate  $\tau/2$  as 0.3 s and  $\lambda$  as  $20\text{ s}^{-1}$ , if  $f = 1$ , for the average intensity of the source at the low-state. In Fig. 2 the variance over the time range of 0.1–1 s is shown to be smaller for higher energies (H band) suggesting that  $\lambda$  is larger or  $f$  is smaller compared to the low energy band.

There are several features of the variability which have to be carefully investigated to see whether they resemble a simple shot-noise model with shot pulses of a constant decay time and size. First, the spectral variation shown by the time profile of the hardness ratio in Fig. 1 cannot be created by a single kind of the shot unless we assume an involved spectral and temporal internal structure of the shot. Second, to explain the difference of  $\eta$  for different energy bands instead of a single kind of shots we have to introduce an artificial ensemble of shots with the variety of spectral hardness: hard shots should be more abundant and smaller in amplitude to reconcile the above results, if  $f = 1$  as generally assumed, and  $\tau$  is constant. If we assume  $f < 1$  as suggested by Sutherland *et al.*<sup>7</sup>, the shot-noise model based on the constant shot can be used. If this were the case smaller  $f$  has to be assigned for higher energies, and a harder spectrum for the steady component compared to the shot-noise component and a negative correlation between the intensity and the hardness ratio are expected: the negative correlation, however, is not clear from this data. Third, the prominent flares can not be accounted for using the shot-noise model. In this experiment the estimated shot rate is about  $20\text{ s}^{-1}$ , if  $f = 1$ , and the model predicts a rapidly decreasing number of the flares with increasing amplitudes. In contrast, the number of the large flares observed is much more than predicted at least for the case of  $f = 1$ . For the case of  $f < 1$ , more complex arguments are necessary concerning the shapes of the large flares and the shots. On one occasion in October 1976 large flares were observed which could not be accounted for by the superposition of the shots regardless of assumed value of  $f$  (ref. 5).

While the shot-noise model is convenient to express the variability features in terms of the parameters and is also an attractive model providing physical implications as for the turbulent nature of the accretion disk, further studies seem necessary before the basic concept of the shot-noise model is firmly established.

Figure 2 indicates the presence of an additional characteristic time scale of  $\lesssim 10\text{ ms}$  for the H component. This is interpreted in terms of the existence of significant pulses of this time scale which will be discussed elsewhere.

## Temperature measurement of interplanetary–interstellar hydrogen

PHOTOMETRIC observations can be used to measure the velocity of the Solar System through an interstellar medium and also provide an accurate method of measuring the temperature of that medium, provided that a very narrow filter is used in order to determine the emission linewidth. We present here the results obtained using a hydrogen absorption cell in conjunction with a Lyman- $\alpha$  photometer contained in the Soviet scientific spacecraft Prognoz-5 which was launched in November 1976. We use only the  $\text{La}$  results to measure the temperature of the interplanetary–interstellar hydrogen. The high result we obtained indicates that the Solar System may be moving through an intercloud medium heated by cosmic- or soft X-rays.

The motion of the Solar System relative to the nearby stars is characterised by a velocity vector  $V$  of  $20\text{ kms}^{-1}$  in the Apex direction,  $\alpha = 271^\circ$  and  $\delta = 30^\circ$ . In this motion, the Solar System is swept by neutral matter of the local interstellar medium. In particular, the flow of interstellar hydrogen atoms was first observed<sup>1,2</sup> through resonance scattering of solar  $\text{La}$  photons (121.6 nm). Helium atoms were also later observed<sup>3</sup> (at 58.4 nm). These observations confirmed the prediction that hydrogen and helium atoms can penetrate deeply into the solar system, because the heliosphere boundary is presumably quite transparent to neutral matter. From the photometric observations at 121.6 and 58.4 nm, it was found that the Solar System motion through the interstellar medium is characterised by a vector  $V_w$ , pointing to a direction  $\alpha = 252^\circ$ ,  $\delta = -15^\circ$ , differing from the Apex direction by  $\approx 50^\circ$ . The density<sup>4</sup> of hydrogen was measured in the range  $0.08\text{--}0.12\text{ atom per cm}^3$  while for helium<sup>3</sup> it was found to be in the range  $0.009\text{--}0.024\text{ atom per cm}^3$ . An estimate of the temperature can also be derived from photometric observation but with considerable uncertainty:  $10^3\text{--}15 \times 10^3\text{ K}$  from  $\text{La}$  photometric observations<sup>4,5</sup>,  $2.5 \times 10^3\text{--}10^4\text{ K}$  from helium observations<sup>3</sup>.

A much more accurate method to determine the temperature is to measure the line width of solar  $\text{La}$  scattered by hydrogen atoms. One attempt was made with the help of *Copernicus* high resolution spectrometer<sup>6</sup>, with a result lying in the range of  $5\text{--}20 \times 10^3\text{ K}$ , rather wide because of the poor photometric sensitivity. Another measurement was obtained<sup>7</sup> from a hydrogen absorption cell placed on board the Soviet probe Mars 7. Though the temperature range was narrowed to  $6\text{--}13 \times 10^3\text{ K}$ , it was still rather large, because of poor knowledge of the direction of sight. The favoured value was  $12 \times 10^3\text{ K}$ .

Results obtained recently with the same technique (a hydrogen absorption cell associated with a  $\text{La}$  photometer) yielded a much more accurate measurement of  $8.8 \pm 1 \times 10^3\text{ K}$  for the temperature of the nearby interstellar medium. The scientific Soviet spacecraft Prognoz 5 was launched on 25 November, 1976 on a very eccentric orbit, with an apogee distance to the centre of the Earth of  $203 \times 10^3\text{ km}$ , and a period of nearly 4d. The spin axis of the spacecraft was pointed toward the sun, and the spin rate was  $3^\circ$  per s. One of the instruments placed on board was a four channel ultraviolet photometer for the study of hydrogen and helium in the interplanetary medium and in the exosphere, through the observation of resonance scattering of solar light at 121.6 nm (H,  $\text{La}$ ), 58.4 nm (He), and 30.4 nm ( $\text{He}^+$ ). The  $\text{La}$  channel looked at  $90^\circ$  from the spin axis, with a field of view of  $1.1 \times 2.7^\circ$  and a 1-s integration time of photon pulses. An absorption cell was placed in front of the photomultiplier.

The apogee of the spacecraft as observed from Earth was nearly in the direction of the North Ecliptic Pole (Fig. 1). The  $\text{La}$  intensity, recorded around the apogee and measured in the plane of rotation of the spacecraft as a function of roll angle  $\phi$ , is shown on Fig. 2. The Earth and its hydrogen geocorona is

**Fig. 1** Configuration of orbit of Prognoz-5 and its spin axis in an ecliptic coordinates system. On 1 December 1976, the Earth was nearly opposite to the direction of  $V_w$ , the velocity of the sun relative to the nearby interstellar medium.

clearly seen from  $\phi = 0^\circ$  to  $\phi = 170^\circ$ , whereas the interplanetary  $L\alpha$  emission is observed from  $\phi = 170^\circ$  to  $\phi = 360^\circ$ , free of any geocoronal contamination.

The absorption cell can be electrically activated, with an optical thickness  $\tau = 8$  and a temperature  $T_c = 300$  K. Thus all of the emission within  $\pm 1.4 \times 10^{-3}$  nm of the  $L\alpha$  wavelength  $\lambda_0 = 121.566$  nm is blocked, and the measured intensity is decreased by a factor  $R$ , the reduction factor. The absorption of the hydrogen cell is large on the geocorona ( $R$  is small) because the geocoronal linewidth is small, whereas the absorption is small ( $R$  is large) on the interplanetary background.

For a pure gaussian emission profile, the reduction factor is only a function of the temperature of emission,  $T$  and of the Doppler shift velocity  $V_D$  between the instrument and the emitting medium. This function can be accurately computed<sup>7</sup> when the hydrogen cell parameters,  $\tau$  and  $T_c$  are known. At apogee, the spacecraft velocity with respect to the Earth is negligible, whereas the Earth's velocity  $V_T$  on its orbit around the Sun is  $30 \text{ km s}^{-1}$  (Fig. 1); therefore there is a strong modulation of Doppler shift  $V_D$  as a function of direction of sight, defined by the roll angle  $\phi$ , the origin of which lies in the ecliptic plane (Fig. 2). We interpret the strong dip of  $R$  around  $\phi_D = 260^\circ$  as a consequence of this modulation.

The observations were made on 1 December 1976, when the spacecraft was practically 'downwind'; therefore the modulation of Doppler shift is essentially caused by  $V_T$  and not by  $V_w$  whose projection on observation plane should be small. We

**Fig. 2** The  $L\alpha$  intensities are plotted as a function of roll angle,  $\phi$  with and without the hydrogen-cell activated.  $\times$ , Cell off;  $\circ$ , cell on. The ecliptic plane lies at  $\phi = 0^\circ$  and  $\phi = 180^\circ$ . The most intense part of the geocorona is not shown. The interplanetary background is clearly seen from  $\phi = 180^\circ$  to  $\phi = 360^\circ$ , opposite to the geocorona. The absorption cell is most efficient at  $\phi_D \approx 260^\circ$ , where the Doppler shift is zero.

assume that the velocity distribution of hydrogen atoms is not perturbed by the sun; therefore at each point of the solar system the emission profile is a pure Doppler profile characterised by  $T$ . The motion of the spacecraft through the interplanetary matter is  $V_{rel} = V_T + V_w$ . When the direction of sight is perpendicular to  $V_{rel}$ , the Doppler shift is zero and the temperature,  $T$ , is directly derived from the measured value of  $R$ . This should occur twice along the great circle of observation, and at these points,  $R$  should be minimum. One point is identified at the angle  $\phi_D = 260^\circ$  where the minimum value  $R_{min}$  is measured, the other is somewhat occulted by the geocorona. In Fig. 3 all the measurements of  $R$  recorded for 2 d

**Fig. 3** All the measurements of the reduction factor,  $R$ , collected during two days are plotted as a function of  $\phi - \phi_D$ . A minimum value of  $R = 0.68 \pm 0.01$  is deduced from this graph, yielding the temperature of the nearby interstellar medium,  $T = 8,800 \pm 1,000$  K.

in the region around  $\phi_D = 260^\circ$  were plotted, yielding a measured value of  $R_{min} = 0.68 \pm 0.01$  from which is derived directly the temperature  $T = 8.8 \pm 1 \times 10^3$  K (taking into account an uncertainty of 10% on  $\tau$ ). This determination, though in the range  $6-13 \times 10^3$  K found with the same technique with Mars 7 is somewhat lower than the favoured value  $12 \times 10^3$  K. But the photometric quality of the present experiment is so much better that we favour this value of  $T = 8.8 \pm 1 \times 10^3$  K.

Such a high temperature of the nearby interstellar medium, associated with the low density of  $\approx 0.1$  atom per  $\text{cm}^3$ , strongly suggest that the Solar System is moving through the so-called

'intercloud medium' (ICM) and confirm the validity of a hot ICM (ref. 8), heated by low-energy cosmic rays or by soft X rays<sup>9,10</sup>.

## Absence of detectable X rays from supercluster candidate 4U0134-11

A CORRELATION between a small subset of high galactic latitude X-ray sources and superclusters of galaxies has been suggested<sup>1</sup>. The existence of superclusters (that is, clusters of clusters of galaxies) was first discussed in the context of optical observations<sup>2,3</sup>. A hot intrasupercluster gas could lead to detectable X-ray emission as well as provide a large fraction of the mass necessary to close the universe<sup>4</sup>. The Goddard Space Flight Center Cosmic X-ray Spectroscopy experiment onboard Orbiting Solar Observatory 8 (OSO 8) scanned directly over the position of 4U0134-11, one of the three 4U sources associated with a supercluster. We did not observe X rays from this source with an upper limit to the source strength a factor of 6 below the catalogued Fourth Uhuru (4U) strength.

Figure 1 represents the path of the OSO 8 spin axis through the region of 4U0134-11. The observation was performed between 7 and 13 July 1976. Catalogued X-ray sources in this region and their error boxes are shown. The detector is a xenon-filled proportional counter, efficient from

Fig. 1 The OSO 8 spin axis scan path during the observation of 4U0134-11. The known X-ray sources and their error boxes are shown. Portions of the scan path used to determine the background rate extend out of the picture.

Fig. 2 Models of the X-ray intensity during the scan path superimposed on the data. Reduced  $\chi^2$  are a, point source 5.1; b, diffuse source, 4.2; c, no source, 1.3.

2 to 60 keV, with an effective area of 237 cm<sup>2</sup> (ref. 5). It is pointed along the spin axis and has a 5° FWHM field of view. The background rate was deduced from the rates at source-free adjacent regions.

The counting rates along the scan path were best fit by a model with a constant X-ray background and no sources. The data (and typical error) are shown in Fig. 2. The three histograms superimposed on the data are: (1) a model with 4U0134-11 as a point source at 2.1 Uhuru counts, the lower statistical limit of its 4U strength; (2) a model with 4U0134-11 as a 2° in radius diffuse source with the same strength; and (3) a model without sources. For each model the deduced X-ray background is added to the count rate and to obtain an upper limit for the strength of 4U0134-11, the strength of 4U0134-09 is set equal to zero. The reduced  $\chi^2$  for the models are 5.1, 4.2, and 1.3 respectively. These results are not sensitive to the absolute level of the background. That is, the no-source model is always by far the best fit. We obtain an upper limit at 99% confidence of 0.4 Uhuru counts for an extended (2° in radius) source at the position of 4U0134-11 (4U value =  $2.7 \pm 0.6$  counts). Because of our large field of view and the motion of our spin axis directly over the source positions, we are not sensitive to positional changes of the sources within their 4U error boxes. Our upper limit at 99% confidence for the sum of the intensities of 4U0129-09 and 4U0134-11 is also 0.4 Uhuru counts.

The X-ray spectrum associated with the supercluster candidates is consistent with a thermal bremsstrahlung spectrum with temperature of more than 10<sup>8</sup> K (ref. 6). Therefore, the fact that the Uhuru detectors<sup>7</sup> are efficient to slightly lower X-ray energies than this OSO 8 detector (1.7 keV rather than 2 keV) does not affect our relative sensitivity to this hard spectrum.

Three high galactic latitude X-ray sources have been identified with superclusters<sup>4,8</sup>. Our observations indicate that one of these, 4U0134-11, is either variable or spurious. Other observations<sup>8</sup> with this detector indicate that it can detect X-ray sources with strengths less than the nominal 4U strength for this object and determine their spectra with comparable observing time. Variability of the X rays from 4U0134-11 on a time scale of ~ years, implying a source

diameter of  $\sim 1$  pc, would rule out a supercluster identification. We have not yet performed observations of the other 4U supercluster candidates.

## Is the Sun a pulsar?

WHILE investigating intensity variations of spectrum-lines of solar origin, periods which seem to describe the Sun's oscillation have been found. The observed period of 2.65 h is very close to 2.78 h, the predicted radial mode fundamental oscillation of the homogeneous model of the Sun. Thus some observations of the solar disk seem to confirm the existence of a radial mode pulsation, while others give no significant indication of such a period. External effects may not, however, have been filtered satisfactorily in all cases. Thus we tried to find an effect of magnetospheric origin that can be related in some way to the described observations. We report here observations of pulsations with period of 2 h 40 min.

Fluctuations of solar origin having a stable period have been noted independently by various observatories<sup>1,2</sup>. From their measurements a characteristic period of 2 h 40 min can be assigned to fluctuations of the central parts of the solar disk. It was established that this event is independent of local time and shows no correlation to the starting time of observation. It is thought that the phenomenon is not due to the apparatus, but originates from the Sun. The observed oscillations can be interpreted as the Sun's pulsations, or perhaps alien effects originating perhaps from the magnetosphere and atmosphere.

The magnetosphere of the Earth can be regarded as a very sensitive measuring probe in the solar wind, which senses every perturbation of solar origin. Thus we investigated variations of the Earth's magnetic field from the viewpoint of effects caused by pulsations of solar origin. There are several magnetic recording systems in the Tihany Observatory<sup>3,4</sup>. We used their data to select several periods to investigate pulsations within the range of periods indicated above.

Magnetically quiet cycles were not considered due to the relative height of local noise level. Records of great magnetic storms were useless as the variations are of large amplitudes and suppress other effects. Hence, we investigated magnetically active days with magnetic variations between 50 and 100 nT.

Diurnal sections from the data arrays of such days were individually analysed. This allowed us to eliminate phase

Fig. 1 Amplitude spectrum of the variations of the geomagnetic field for 10 November 1975 in the range of periods from 20 to 200 min.

springs which affected the analysis. Thus an amplitude spectrum characteristic of the diurnal part of the selected magnetically active days was obtained as shown in Fig. 1. An amplitude peak is seen to rise by a maximum of several nT out of the average noise level in the environment of the period 2 h 40 min. Most of the investigated days gave a similar result. In Fig. 2 is shown the mean spectrum for 9–11 November 1975. On several occasions no significant rising amplitude peak was found on the noise level background.

These results can be interpreted as follows. We assume that the period of 2 h 40 min is of solar origin, during magnetically active cycles the magnetosphere of the Earth and the magnetic lines of force of the interplanetary field intertwine.

Such a connection means that magnetic field variations originating from the Sun's pulsation, which in the interplanetary space reaches as far as the magnetosphere, perturb the geomagnetic field. This can be observed on magnetic records in the observatories. Since the oscillation observed on the Sun's surface corresponds to magnetic variations of Gaussian magnitude, variations of several nT ( $10^{-5}$  G) amplitudes are possible on the Earth's surface.

During magnetically quiet cycles the magnetosphere is closed, there is no merging, and so no pulsation of solar origin can be observed. During magnetic storms, however, the noise level rises to such an extent that, although the merging exists, no significant amplitude could be detected around the above period.

We do not know whether spectrum lines investigated by the astrophysical observatories are insensitive to magnetic effects in a way that they are not affected by disturbances of the magnetosphere. If this were possible, then the possibility of a pulsation of a so far unknown terrestrial magnetospheric origin cannot be excluded. Hence the observed spectrum lines may be influenced by such a pulsation, which may have seemed to be of solar origin.

Thus, if the possibility that spectrum lines with 5,123.7 Å wavelength can be affected by geomagnetic field variations is excluded, then the magnetic variation with a period of 2 h 40 min

Fig. 2 Mean amplitude spectrum of the variations of the geomagnetic field for the cycle 9–11 November 1975.

originating from the magnetosphere presents an indirect proof of the Sun's oscillations. Thus the Sun with nearly homogeneous distribution of density has a radial mode fundamental oscillation within the range of the above period. At the same time this phenomenon may prove that the interplanetary and terrestrial magnetic field merge.

For a final conclusion to be reached, however, the observed spectrum line of solar origin must be examined for its sensitivity to variations of the geomagnetic field. If it is insensitive, the possibility of a magnetospheric effect can be excluded.

## Short-term influence of anthropogenic sources on tropospheric baseline lead

ESTIMATING tropospheric baseline lead requires relatively long collection periods using conventional high volume methods because the airborne concentrations are very low in comparison with levels found in urban areas. During such collections, anthropogenic sources of lead may be present for short periods leading to apparently high results, even at remote locations such as the mid-Pacific Ocean<sup>1</sup> and Antarctica<sup>2</sup>. Significant geographical variations in soil-sized Pb particles were also related to anthropogenic sources affecting the distribution of lead in marine atmospheric particulates<sup>3,4</sup>. We describe here investigations using furnace atomic absorption spectrometry (AAS) of the lead content in the atmosphere around Cape Grim, Tasmania.

High volume particulate collections give average results which do not account for atmospheric changes occurring over a few hours because of the collection times required. Limitations are also imposed by the sensitivity of the analytical technique for lead determination and the blank levels of filter media used. Furnace atomic absorption spectrometry (AAS) has been proposed as a suitable technique for the determination of background atmospheric lead particulates<sup>5</sup>, using the graphite furnace atomiser as the particulate collection device and taking advantage of the extremely high sensitivity for lead and small air sample volumes required. We have used graphite cups in the dual role of collection device and furnace atomiser, using micro air-sampling techniques based on earlier work<sup>6-8</sup> to follow atmospheric lead concentration over short periods of time, 7 h (but 3-10 min in urban areas) using a consecutive series of individual samples. The graphite cups (RW1 grade Ringsdorff Werke) gave the unique advantage of a filter with a zero blank for lead which can be transported to and from the sampling location without contamination<sup>9</sup>.

The site for sampling was the Australian Baseline Atmospheric Pollution Station (Department of Science) at Cape Grim, North West Tasmania, located in the Southern Hemisphere as shown in Fig. 1a. The station is situated on the edge of a cliff, 90 m above the sea and receives western maritime winds which travel over the Southern Ocean at this latitude. But winds travelling around high pressure centres (counter-clockwise air flow in the Southern Hemisphere) and within 90° of north east may be subjected to anthropogenic lead sources from urban-industrial sources in Tasmania and the mainland of Australia (Fig. 1b).

A series of 15 consecutive samples were taken over five days (Table 1 and Fig. 2). Other measurements taken on site, over the

same period, were a high volume sample (Table 1), meteorological data (Fig. 2) and a comparison of hygroscopic (sea-salt) particles and non-hygroscopic particles per unit volume (Table 2).

Meteorological data for the period 14-16 May (Fig. 1) showed a steady easterly wind (low wind speed) proceeding towards Cape Grim from the urban-industrial centres along the northern coastal area of Tasmania. This apparently has a strong influence on the total particle concentration (Table 2). Between 16 and 17 May the wind reversed direction (easterly to westerly). Sampling of lead particulates was started then.

Samples 1-4 showed very high atmospheric lead concentrations which seemed to be anomalous at first examination. The reversal of the steady air mass, however, from the previous few days was associated with precipitation (rainfall) on 16 and 17 May and caused the atmospheric lead concentrations to be as high as typical urban levels. The influence of precipitation is also apparent from the particle data (Table 2).

Following the cessation of precipitation (sample 4) and the displacement of all impure air, the westerly winds brought very clean maritime air to Cape Grim and the atmospheric lead concentration fell to very low levels (samples 5-12). The total particle concentrations (Table 2) from late on 17 May until the middle of 21 May were the lowest for the whole period.

On 20 May a wind change to north-north westerly direction led to an increase in atmospheric lead concentration (samples 13-15) but in this instance directly following the wind change, implicating the influence of anthropogenic sources. This was also

Mean	Samples 1-15	$0.037 \pm 0.059 \mu\text{g m}^{-3}$ Pb		
Mean	Samples 5-12	$0.0033 \pm 0.0024 \mu\text{g m}^{-3}$ Pb (base line)		

Analysis for Pb furnace AAS was performed using the Varian Techtron Model 63 CRA following addition of  $2 \mu\text{l}$   $1,000 \mu\text{g ml}^{-1}$   $\text{H}_3\text{PO}_4$  to each cup and Pb standards in 20%  $\text{HNO}_3$  (double distilled). The Model 63 CRA workhead was mounted in a Model 1200 AAS which was set to the 217.0 nm Pb resonance line and 1.0 nm slit. Non-atomic absorption was negligible. Detection limit for 10-l air sample was  $0.0036 \mu\text{g m}^{-3}$  Pb and  $> 20 \text{ l}$  air was sampled for baseline conditions, identified from on-site meteorological equipment. Total volume of air passed through each cup with a Millipore Type XX60 220 50 pump, was measured using an American Dry Type Test Meter (Model DTM 115) because flow-rates through individual cups were variable (range  $0.028-0.31 \text{ l min}^{-1}$ ). During preparation each sample and blank cup was fired through the atomiser cycle for Pb to check that contamination was at blank level before placing in Teflon adapters and glass containers<sup>9</sup> and transportation to sampling site. Dimensions of RW1 grade graphite cups are as described for other cups<sup>8</sup>.

High volume air sample (Kimoto HVA and Whatman GF/A glass-fibre filter) 0804 h 17 May-0717 h 22 May  $0.0056 \pm 0.0011 \mu\text{g m}^{-3}$  Pb. Measurement of air flow-rate was made twice daily during the collection period and used to calculate the volume of air sampled ( $9,692 \text{ m}^3$ ). Whatman GF/A filter was divided into two and extracted with 10 ml 20%  $\text{HCl}$  and 40 ml 40%  $\text{HNO}_3$  (both high purity) in a Soxhlet extractor for 3 h. Solution was taken to near-dryness and made up with 10%  $\text{HNO}_3$  to 50 ml after filtering. Average of 4 filters, treated similarly, was taken for blank. Pb was determined with Pye-Unicam Model SP1950 AAS incorporating automatic background correction and gave a detection limit of  $0.0008 \mu\text{g m}^{-3}$  Pb (217.0 nm Pb resonance line), in this case.

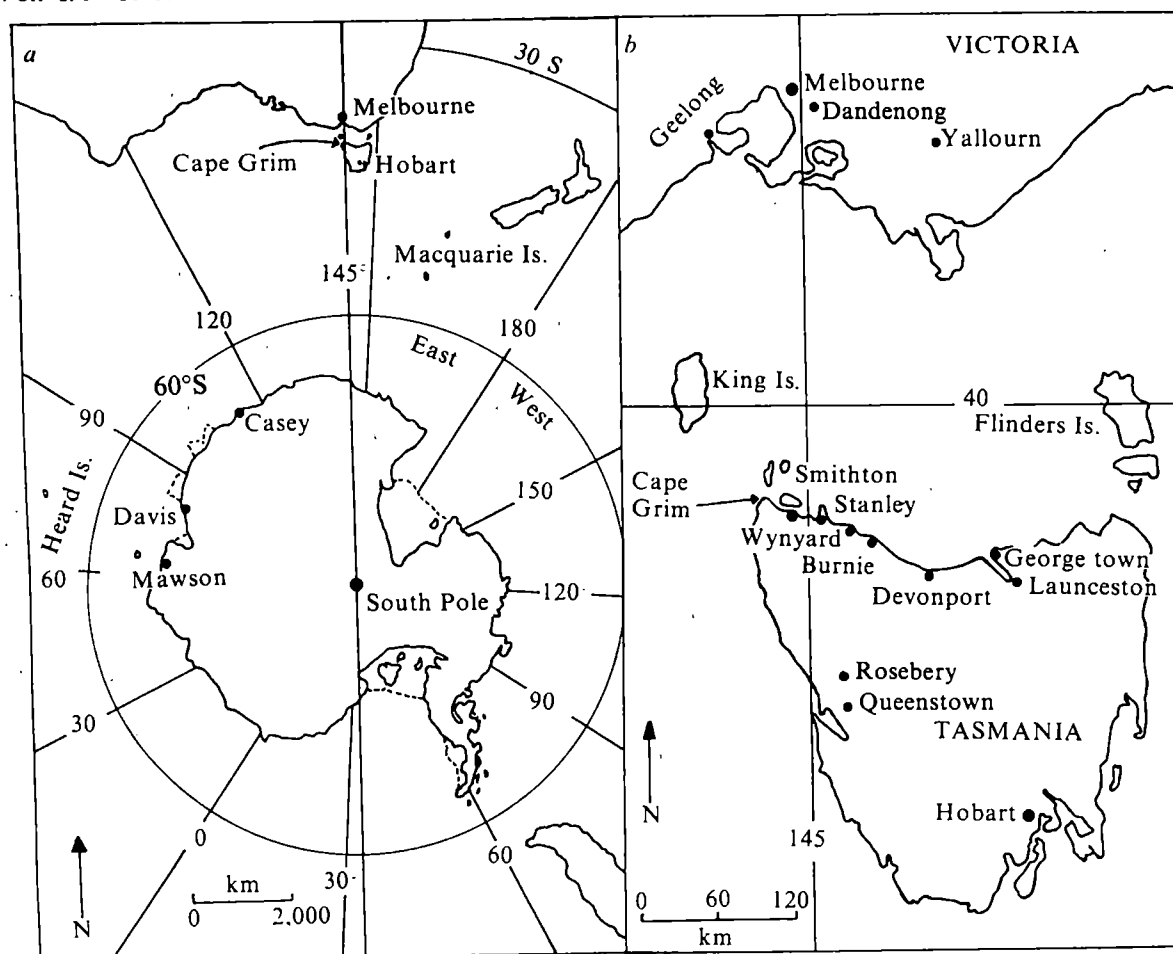

Fig. 1 Location of Cape Grim in relation to *a*, Southern Hemisphere and *b*, Urban and industrial centres of Tasmania and the mainland of Australia.

associated with a dramatic increase in total particle concentration (Table 2) compared with sea-salt particle concentration demonstrating the interaction of air from an urban origin with the background air and the importance of meteorological data in interpreting the atmospheric lead results.

The efficiency of graphite as a filtration medium may be judged by comparing the mean for samples 1–15 ( $0.037 \mu\text{m}^{-3}$  Pb) with the high volume sample result ( $0.0056 \mu\text{m}^{-3}$  Pb). Both figures include lead from anthropogenic and background origins and hence the high volume figure is not indicative of baseline atmospheric concentration. Glass-fibre filters as used in high volume samplers, are reported to be greater than 99% efficient for di-(2-ethylhexyl)phthalate particles ( $0.3 \mu\text{m}$  in diameter) at a flow rate of  $0.1 \text{ ml min}^{-1}$  (ref. 10). Comparison of graphite with common filter media, including glass-fibre for urban atmospheric lead particulates, showed graphite to be a much more efficient filter material, presumably because it retains a larger proportion of sub- $\mu\text{m}$  lead-containing particles<sup>11</sup>. Studies of size distributions of airborne particles at various urban and non-urban locations are almost always multi-modal<sup>12</sup> and considerable proportions of particles can be in the size range  $0.05$ – $1.0 \mu\text{m}$ . The size distribution of the smaller particles (Table 2) (including lead) has a mode between  $0.01$ – $0.05 \mu\text{m}$  diameter in polluted conditions and may be as great as  $0.1 \mu\text{m}$  or larger in clean conditions (E. K. Bigg, personal communication). Sea-salt particles (Table 2), by comparison, have a modal diameter of about  $1 \mu\text{m}$  and rarely have diameters below  $0.3 \mu\text{m}$ . This information supports the theory that the glass-fibre filter collection (Table 1) was not retaining a large proportion of sub- $\mu\text{m}$  lead-containing particles. Particles of the order of  $0.1 \mu\text{m}$  will have longer atmospheric residence times compared

with those less than  $0.01 \mu\text{m}$  or greater than  $10 \mu\text{m}$ , which tend to agglomerate, be washed out, or become 'fall-out'.

The mean figure for samples 5–15 ( $0.0033 \mu\text{m}^{-3}$  and equivalent to  $3.3 \text{ ng per SCM}$ ) describes the background atmospheric lead concentration at Cape Grim for the period sampled and compares in magnitude with data from the remote HASL Southern Hemisphere stations<sup>13</sup> (Easter Island, Antarctica (Chilean stations), South Pole station) for the period 1966–1976.

Table 2 Nature of air particles at Cape Grim (comparison of hygroscopic with non-hygroscopic particles)

15	0.66/—	0.60/576	—/—	—/—
16	2.9/432	3.1/—	3.2/—	3.6/272
17	3.4/344	—/—	—/—	4.7/144
18	4.4/—	4.2/—	4.8/160	3.8/—
19	3.6/154	—/—	—/—	3.6/164
20	2.4/150	—/—	—/256	1.8/—
21	2.6/—	3.6/128	3.7/—	4.1/936
22	—/—	—/—	—/—	3.4/126

Lead particulates are associated with non-hygroscopic particles (difference of sea-salt and total particles) but particles from urban sources are very often mixed. Sea-salt particles form about 0.1% (numerically) of particles in polluted conditions and strictly non-hygroscopic particles; 0.1–10%. Most non-sea-salt particles usually have a hygroscopic coating (E. K. Bigg, personal communication).

\*M is salt particles  $\text{cm}^{-3}$  (hygroscopic) and N is total particles  $\text{cm}^{-3}$  (electrostatic precipitator) as weighted running mean over at least 24 h. (E. K. Bigg, personal communication.)

Fig. 2 Diurnal variations of atmospheric particulate lead, wind speed and direction, temperature and precipitation at Cape Grim. *a*, Precipitation for whole hour; *b*, temperature for minutes 6–9 of the hour; *c*, mean wind direction for minutes 3–6 of the hour; *d*, mean wind speed for minutes 0–3 of the hour; *e*, atmospheric particulate lead. (Data other than lead from E. K. Bigg.)

The latter (mean monthly composite high volume samples) are higher in many cases because they represent ambient air lead concentrations with probable anthropogenic contributions rather than background alone. Comparison with other data from carefully selected sampling periods at the South Pole station<sup>14</sup> (mean 0.63 ng per SCM, range <0.19–1.2 ng per SCM) shows the Cape Grim figure to be higher. A possible explanation for the higher Cape Grim atmospheric lead concentrations may be the higher collection efficiencies achieved thereby.

We thank the Tasmanian State Department of Environment for financial assistance, the Australian Department of Science for use of the Australian B.A.P.S. Cape Grim, assistance from Dr G. I. Pearman and other personnel at CSIRO Division of Atmospheric Physics, Dr E. K. Bigg, CSIRO Division of Cloud Physics for use of meteorological and particle data and helpful comments and Michael Power for help with the analyses.

## Palaeoanisotropy in the upper mantle

CARTER<sup>1</sup> has reviewed advances in understanding the steady-state flow of rocks with particular reference to the behaviour and anisotropic alignment of rocks in the upper mantle. Some form of high-temperature creep is clearly responsible for the distribution of continents and their first-order structures<sup>2</sup>. The difficulty is specifying the exact mechanism and the possible anisotropic alignments. Appropriate upper mantle temperatures and pressures can be achieved in the laboratory<sup>3</sup>, but any results must be extrapolated to rates of deformation lower by some five or six orders of magnitude. Carter *et al.*<sup>2</sup> conclude, although there are conflicting views<sup>4</sup>, that the syntectonic recrystallisation suggested by Avé Lallemant and Carter<sup>5</sup> is the dominant deformational process. This will be most effective at the higher temperatures at the base of the lithosphere where crystals, orientated by the deformations, have their alignments fixed as the lithosphere cools. All the deformational processes suggested for the upper mantle are capable of orientating crystalline structures, and aligned azimuthal-anisotropy may be expected at any depth in the lithosphere.

It is difficult to make accurate observations of the upper mantle, but whenever the lithosphere has been examined in sufficient resolution it is found to be anisotropic. Occasionally upper mantle material can be examined in the laboratory. Peselnick *et al.*<sup>6</sup> measure up to 7% velocity anisotropy in lherzolite xenoliths from the Sierra Nevada, which are estimated on compositional grounds to have originated at 50 km depth in the upper mantle. The only way *in situ* information can be obtained, however, is from seismic observations. Existing observations of azimuthal anisotropy in the upper mantle are of three types<sup>7</sup> (1)  $P_n$  velocity anisotropy, widely observed beneath the oceanic crust, and now beneath the Rhinegraben<sup>8</sup>, could be the result of as little as 5 km of anisotropic material beneath the mocho. (2) Velocity anisotropy of fundamental-mode surface-waves in the NAZCA Plate<sup>9</sup> is attributed to anisotropy extending down possibly to the top of the low-velocity-zone at about 125 km depth. (3) Polarisation anomalies of second-mode surface-waves across Eurasia<sup>10</sup> indicate at least 10 km of anisotropic material. These seismic observations establish anisotropy in the top few kilometres of the lithosphere, but, except for type (2) observed in one area only, give no indication of the vertical range.

There seem to be two main possibilities for the configuration of anisotropic alignments throughout the lithosphere in any given region. In uniform alignment, there will be little variation with depth of the alignment in the lithosphere, regardless of the tectonic history, if there is a deformation process which can modify the alignment, perhaps very slowly, to conform with the existing stress pattern over the past few million years.

In layered alignment, the alignment of the lithosphere will vary with depth if the alignment at the lower higher-temperature lithospheric boundary is permanently fixed as the lithosphere cools. This will result in the lithosphere having layers with different alignments corresponding to stress or flow patterns at some epoch in the past when the physical conditions were suitable for realignment to occur.

If syntectonic recrystallisation<sup>1,2,5</sup> is the dominant alignment process and there is no subsequent deformation, the layered configuration will persist, and palaeoanisotropy in the upper mantle will be preserved over long periods of time. In regions of comparatively young lithosphere such as that beneath the oceans, where the forces acting on the lithosphere have been substantially the same throughout its history, the alignment will be uniform. Carter<sup>1</sup> finds that the plastic deformation processes of Hess<sup>11</sup> and Francis<sup>12</sup> give rise to similar fabrics as syntectonic recrystallisation, and remarks that the question of which process is dominant is now less important. But, the process which produces the existing alignments and its period of

activity, is still fundamental to the interpretation of the anisotropic configuration of the lithosphere.

We see that to achieve a substantial realignment by any of the various processes in the given physical conditions, the relative time-constant determines which configuration exists. It is difficult to believe that any *a priori* arguments derived from surface experiments will clearly distinguish between configurations resulting from slow deformations in the upper mantle acting over hundreds of millions of years. Observations of the presence, absence, and variation of anisotropic alignments at different depths beneath oceans and continents may, therefore, be crucial in deciding the deformation processes and the tectonic history of the lithospheric upper mantle.

Numerical calculations<sup>10,13,14</sup> demonstrate that most seismological measurements are very little affected by even substantial amounts of anisotropy. The only diagnostic difference, between propagation through anisotropic and propagation through isotropic structures, is the coupling in the presence of anisotropy between polarisations in the radial-vertical plane and the transverse-horizontal direction. This coupling provides a technique for investigating deep anisotropy: body waves passing through anisotropic structures generate polarisation anomalies at each interface, which may be interpreted in terms of depth, thickness, orientation, and degree of anisotropy<sup>13,14</sup>. These anomalies are likely to be subtle and difficult to observe but they provide probably the only means of examining the *in situ* palaeoanisotropy in the lower lithosphere.

This work was supported by the Natural Environment Research Council. I thank Dave Bamford for helpful discussions, and Lou Peselnick for a preprint.

## Giant haloes in mica

MUCH attention has been given to the origin of 'giant' pleochroic haloes found in a number of minerals, especially micas<sup>1–6</sup>. Normal pleochroic haloes are due to the effects of radiation damage from  $\alpha$ -particles emitted from small inclusions at the centre of each halo, and the largest radius of the halo is determined by the range of the  $\alpha$ -particle of highest energy, which is that from <sup>212</sup>Po in the case of a thorium-rich inclusion. These have an initial energy of 8.78 MeV. The giant haloes seem to be of two kinds. In Gentry's sample<sup>7</sup> ~40% have a discrete radius ~54  $\mu$ m and he reports them to be invariably associated with dense thorium haloes. This group appears properly to be associated with production by the well-known but rare (~1.3  $\times 10^{-4}$ ) pair of long range  $\alpha$ -particle groups from <sup>212</sup>Po at ~10.5 MeV. The remaining giant haloes have a monotonic distribution in radius extending up to 110  $\mu$ m; they have been interpreted in terms of diverse processes such as extinct radiations of higher energy, proton knock-ons by  $\alpha$ -particles,

knock-ons from neutrons, channelling, migration of the parent radioactive material, but we report one natural and simple explanation which seems not to have been considered.

The giant haloes (illustrated, for example, in ref. 4) are also outstanding in that there is a large inclusion. Such large inclusions in mica, which is well known for the readiness with which it may be cleaved, seem very likely to be surrounded by a cleavage crack lying in the natural crystallographic cleavage plane, and presumably filled principally with H<sub>2</sub>O. The plane of the crack would pass close to the inclusion centre. Such a crack could well be initiated by changes in temperature or pressure at some stage during the life of the specimen, or possibly by swelling of the inclusion due to the high degree of radiation damage that it receives. If cracks radiating from the inclusion have propagated in planes approximately normal to the natural cleavage plane, as apparently happens in the haloes illustrated in ref. 3 and in Fig. 2 of ref. 4, then cracking parallel to the natural cleavage is extremely likely.

It seems reasonable that the surrounding crack in the cleavage plane could have an opening height,  $h \geq 0.1 \mu$ m at the boundary of a large inclusion, and extend up to perhaps 50  $\mu$ m outwards in the case of the largest inclusions. (Cracks with smaller openings, could possibly heal gradually, if a little plastic deformation of the mica can occur, and they are not kept open by intrusion of solid particles. With larger openings, stabilisation of the opening by inflow of debris becomes more likely. The clearly visible cracks normal to the cleavage plane (shown in refs 3, 4) must have  $h$  well exceeding our suggested lower limit.)

Cracks such as we consider here would help extend the volume exposed to radiation damage in two ways: (1) by allowing  $\alpha$ -particles entering or crossing the crack nearly parallel to the cleavage plane to travel a significant fraction of their range in H<sub>2</sub>O; and (2) by enhancing the capabilities of diffusion of the radon isotopes in radioactive equilibrium with the inclusion, some of which will be liberated following the recoil at their formation from their parent radium nucleus.

To be effective in extending the range of the  $\alpha$ -particles the crack has to possess sufficient height so that  $\alpha$ -particle scattering in the water can be ignored. For this simplifying approximation to be adequate it is necessary that  $h \geq 5 \times 10^{-4} x^{3/2}$  where  $x$  is the path length in H<sub>2</sub>O and both  $h$  and  $x$  are measured in  $\mu$ m. The range extension thus endowed to the  $\alpha$ -particles is close to 50% of the distance travelled in H<sub>2</sub>O since  $\alpha$ -particle ranges in H<sub>2</sub>O are close to twice those in both biotite and muscovite micas. The proportion of  $\alpha$ -particle tracks stopping in the crack plane that have a range extension appropriate to maximum passage through H<sub>2</sub>O will be of the order of  $h/2a$ , where  $a$  is the radius of the inclusion; this figure can, of course, be much larger than  $1.3 \times 10^{-4}$  which is the abundance of the naturally occurring 10.5 MeV long-range  $\alpha$ -particles.

With a half-life of ~52s, <sup>220</sup>Rn liberated from a thorium-rich inclusion has sufficient time to diffuse over the full extension of the volume of the crack, taking a diffusion coefficient equal to ~10<sup>-5</sup> cm<sup>2</sup>s<sup>-1</sup>, so that the polonium  $\alpha$ -particles, in particular, should have an origin that is more extended than the volume of the inclusion. This is also true for the uranium-rich inclusions, where <sup>222</sup>Rn has a half-life of 3.8 d. Such diffusion is very obvious in 'thorium stars' produced by radioactive impurities in nuclear emulsion. These are tracks of successive  $\alpha$ -particles produced in the decay chain from single nuclei of <sup>224</sup>Ra and <sup>228</sup>Ra which have an abundance of ~3  $\times 10^4$  cm<sup>-3</sup> in normal nuclear emulsion, Brown and Fowler, in ref. 8.

With each of these mechanisms the halo produced should not be spherical. It should have a radius of normal magnitude perpendicular to the cleavage plane. In the case of enhancement by  $\alpha$ -particle propagation along the plane of the crack, the fully enhanced radius of the halo should be restricted to a band of thickness  $\Delta Z \sim h$  the crack opening, whereas if enlarged by radon diffusion the enhancement would spread over a thickness  $\Delta Z$  of the order of the range of the subsequent polonium  $\alpha$ -particles. Quantitative information about the form of the

halo in this third dimension would be most valuable in attempting to determine which mechanism is in fact important in the generation of these giant haeles.

## Mobility of pyroclastic flows

THE mobility of pyroclastic flows has been described as spectacular<sup>1</sup>, in particular because of their ability to surmount obstacles in their path. It is relatively easy to estimate the minimum velocities required to climb a given height, if frictional losses are ignored. We have used data on well documented large cold rock avalanches to estimate the magnitude of frictional losses, and used these estimates to calculate velocities for some large pyroclastic flows. We argue that frictional losses in large pyroclastic flows must be comparable with, or less than, those in the most mobile rock avalanches, and calculate from data on heights climbed that velocities of large pyroclastic flows may be very high, up to 140 m s<sup>-1</sup>. We also conclude that the height of the eruption column giving rise to a large pyroclastic flow need only be a few hundred metres in some cases.

It is difficult to investigate the mobilities of large pyroclastic flows, such as those forming ignimbrites, since none has ever been observed in eruption. Only a few relatively small *nuée ardente* eruptions have been observed directly. Some of the largest ignimbrites have volumes of the order of 100 km<sup>3</sup>, extend for horizontal distances over 100 km (ref. 2), have climbed obstacles up to 600 m in height and have been estimated to travel at speeds up to 100 m s<sup>-1</sup> (ref. 3).

The scanty previous literature on mobility of pyroclastic flows has been summarised by Sparks<sup>3</sup> and Miller and Smith<sup>1</sup>.

Fig. 1 Horizontal distance travelled for well documented large rock avalanches and ignimbrites plotted against volume. □, rock avalanches; ▲, Central Andes ignimbrites; ●, other ignimbrites.

We have obtained some further data from the Central Andes, where three ignimbrites are known which have climbed obstacles up to 350 m high<sup>2</sup>. The way in which pyroclastic flows surmount obstacles has been disputed<sup>3</sup>. Recent observations on the upward concentrations of pumice clasts in ignimbrites imply high flow densities<sup>3</sup>; that is, pyroclastic flows may behave in a similar way to large rock avalanches.

For rock avalanches greater than about 10<sup>-3</sup> km<sup>3</sup>, Hsü showed that mobility is related to the volume—the largest being the most mobile<sup>4</sup>. Hsü explained the unusual mobility of large rock avalanches in terms of fluidisation of fine debris by entrapped air; Shreve in contrast suggested that rock avalanches travel on a cushion of trapped, compressed air<sup>5</sup>. Whatever the mechanism, the efficiency of the process seems to increase with the size of the moving body.

Many ignimbrites have volumes comparable with or greater than the largest known rock avalanches, some having volumes in excess of 100 km<sup>3</sup> (ref. 6). The very high mobility of the pyroclastic flows giving rise to such deposits can be inferred from Fig. 1, where horizontal distance travelled is plotted against volume for pyroclastic flows and large rock avalanches. The large volume ignimbrites plot in a distinctly more mobile field than all but the largest of the rock avalanches.

Although there are a few direct measurements on the velocities of small *nuée ardentes*—up to 60 m s<sup>-1</sup> (refs 7 and 8)—the velocities of the much larger volume pyroclastic flows can only be inferred from their climbing ability. Simple calculations, based on the conversion from potential to kinetic energy, can be done which relate the horizontal velocity to the height climbed. By this means, Sparks showed that a minimum velocity of the order of 100 m s<sup>-1</sup> is required for a pyroclastic flow to climb a 600 m high obstacle<sup>3</sup>. Such calculations take no account of frictional losses. We have obtained crude estimates of these losses in pyroclastic flows by looking at data for much better known rock avalanches. In the case of a body of rock travelling down one slope and up an opposing one, an estimate of the overall percentage frictional loss ( $F$ ) can be derived, from the interconversion of potential energy and kinetic energy, by including frictional loss in the appropriate formulae

$$\begin{array}{lcl} \text{kinetic energy gained} & = & \text{potential energy lost} \\ \frac{1}{2}mv^2 & & \left(\frac{100-F}{100}\right)mgh_1 \end{array}$$

$$\begin{array}{lcl} \text{potential energy gained} & = & \text{kinetic energy lost} \\ mgh_2 & & \left(\frac{100-F}{100}\right)\frac{1}{2}mv^2 \end{array}$$

where  $m$  = mass;  $v$  = velocity,  $F$  = percentage frictional loss,  $h_1$  = height lost;  $h_2$  = height gained

$$\text{from which} \quad F = 100 \left(1 - \left(\frac{h_2}{h_1}\right)^{\frac{1}{2}}\right)\%$$

Clearly, the calculated value of  $F$  will be increased if the flow travels a large horizontal distance between the two slopes, or if the main direction of travel is oblique to the slope climbed. Relevant data for the best known rock avalanches are listed in Table 1. In the more mobile of these  $F$  is between 40 and 60%. In Fig. 2 we have plotted the theoretical relationship between horizontal velocity and height climbed for values of  $F$  between 0 and 60% (solid lines).

Taking the data summarised in Fig. 1 into account, large pyroclastic flows are likely to have values of  $F$  comparable to, or even lower than, the most mobile rock avalanches, that is, in the range 30–40%. On this basis, the velocities required for the obstacle climbing ignimbrites plotted on Fig. 2 would be in the range 85 to 140 m s<sup>-1</sup>. These values are realistic: the errors not

Table 1 Height data and values of  $F$  for documented large rock avalanches

Name	Volume (m <sup>3</sup> )	Height descended $h_1$ (m)	Height climbed $h_2$ (m)	$F$ (%)	Remarks
Elm <sup>4</sup>	$1.1 \times 10^7$	450–560	100	50–55	
Little Tahoma Peak <sup>9</sup>	$1.1 \times 10^7$	1,250–1,890	40–90	75–85	Climbed oblique slope

Madison <sup>11</sup>	$2.9 \times 10^7$	400	120	45	
Frank <sup>5</sup>	$3.7 \times 10^7$	760–920	120	60–65	
Silver Reef <sup>6</sup>	$2.2 \times 10^8$	1,000	45	80	Travelled a long horizontal distance
Blackhawk <sup>6</sup>	$2.8 \times 10^8$	1,220	60	80	Travelled a long horizontal distance
Saidmarreh <sup>11</sup>	$4.3 \times 10^9$	1,520	460–610	35–45	

taken into account in our simple model would only increase the values of  $F$ , and therefore the velocities required. Such high velocities have two important implications.

First, the emplacement of even a very large ignimbrite sheet could take place in a very short time, that is minutes rather than hours. This is particularly relevant in considering the mechanisms of transport of pyroclastic flows, and the origin of textures within them, such as the sorting of pumice fragments. Second, if values for  $F$  for pyroclastic flows giving rise to ignimbrites were around 30–40%, indicating efficient lubrication of the flow by fluidised fine grained material, it is not necessary to invoke collapse from eruption columns of exceptional height

Fig. 2 Theoretical relationship between horizontal velocity at base of climb and height climbed for values of  $F$ : a,  $F = 60\%$ ; b,  $F = 50\%$ ; c,  $F = 40\%$ ; d,  $F = 30\%$ ; e,  $F = 0\%$ ; using the

expression  $V = 10 \left( \frac{2gh_2}{100F} \right)^{1/2}$ . Also plotted are estimated velocity

ranges for individual ignimbrites assuming values of  $F$  between 30 and 40%: A, Aniakchak<sup>1</sup>; U, Ujina<sup>2</sup>; C, Carcote<sup>2</sup>; F, Fisher<sup>1</sup>; CI, Campanian<sup>3</sup> and Ito<sup>3</sup>.

to account for the high speeds. For example, collapse from a comparatively modest column 400–500 m high would be sufficient to account for the mobility of the Ujina ignimbrite. In other cases, where the pyroclastic flow travelled a substantial distance horizontally before surmounting an obstacle, the frictional losses would have been greater, and therefore the mobility of the flow must have been achieved by collapse from an eruption column of comparatively great height.

## Ratio of prey to predators in community food webs

WHETHER the diversity of resources limits the diversity of consumers, and specifically, whether the number of kinds of prey limits the number of kinds of predators, has been of continuing interest in theoretical ecology and wildlife management<sup>1–3</sup>. Food webs from the ecological literature were collected in machine readable form to study this question empirically. We report here that in community food webs, the ratio of the number of kinds of prey to the number of kinds of predators seems to be constant, near 3/4. This invariance has not been noticed in earlier studies of individual cases.

Before analysis, food webs were characterised as one of three types—community, sink and source. Community food webs describe all kinds of organisms (possibly restricted to some location, size or taxa) in a habitat, without reference to the eating relations among them. Sink food webs describe all the prey taken by a set of one or more selected predators, plus all the prey taken by the prey of those predators, and so on. Source food webs describe all the predators on a set of one or more selected prey organisms, plus all the predators on those predators, and so on. Sink and source food webs, hypothetical or schematic constructions, and avowedly incomplete, partial or tentative food webs were excluded from further study. Fourteen community food webs were thus selected. The complete data and individual cases will be discussed elsewhere<sup>4</sup>. When the report of a food web contained ambiguous or uncertain information about a

feeding relation, the web was included in two versions, one based only on the unambiguous information and the other incorporating the additional uncertain or probable eating relations. The analysis presented here based on all versions, makes no claim that the data points are statistically independent and attaches no probability values to the statistics calculated.

The food webs describe the diets or predators not of individual organisms but of kinds of organisms. A 'kind of organism' may be a stage in the life cycle or a size class within a single species, or a collection of functionally or taxonomically related species, according to the practice of the original report. The numbers in the following analyses refer to these ecologically defined kinds of organisms, not necessarily to any conventional taxonomic unit. A predator is defined as a kind of organism that consumes at least one kind of organism included in the food web. A prey is defined as a kind of organism that is consumed by at least one kind of organism in the food web. Some kinds of organisms may be both predators and prey.

In community food webs, the number  $m$  of prey is very nearly proportional to the number  $n$  of predators (Fig. 1). A least squares regression of  $m$  against  $n$  gives

$$m = 1.79 + 0.71n \quad (1)$$

The sample standard deviation of the regression coefficient is 0.07 and the linear correlation coefficient between  $m$  and  $n$  is 0.90. The standard error of estimate, or sample standard deviation from regression, is 4.62. As is obvious from Fig. 1,

Fig. 1 The number of kinds of prey and the number of kinds of predators in community food web versions.

the regression may be well approximated by a straight line through the origin. The least squares regression is

$$m = 0.77n \quad (2)$$

The proportionality between the number of prey and the number of predators in Fig. 1 is based on 24 versions of 14 food webs reported over a period of decades. When the food webs were collected and encoded it was not known that such a simplicity would emerge. It therefore seems likely that this invariance in the proportions of predators and prey represents a fact about nature, rather than an artefact of collusion or convention.

Given that the proportion of prey to predators is a scale-invariant feature of community food webs, the proportion can be predicted quantitatively from other facts. For a given food web with  $m$  prey and  $n$  predators, let  $A$  be the number of predator-prey couples. (If  $X$  eats  $Y$  and  $Y$  eats  $X$ , the couples  $(X,Y)$  and  $(Y,X)$  are counted as distinct. If  $X$  eats  $X$ ,  $(X,X)$  also counts as a couple. In the conventional graphical representation of a food web,  $A$  is the number of directed arrows from prey to predator.) Then within any food web

$$A = (\text{average prey per predator}) \times n \\ = (\text{average predators per prey}) \times m \quad (3)$$

The grand mean over all 24 community food web versions, weighting each food web equally, of the average prey per predator is 2.418; the grand mean of the average predators per prey is 3.199. If these means apply to each food web, then substitution into equation (3) predicts

$$m/n = 2.418/3.199 = 0.756 \quad (4)$$

which differs trivially from the least squares regression in equation (2).

The simplicity of the argument from the proportionality between  $m$  and  $n$  to equation (4) may raise a suspicion that its success depends on an arithmetical fact rather than on the observed invariance of proportions of predators and prey in nature. A numerical example disproves this suspicion. Suppose a sample of community food webs consisted of two food webs. Suppose the first food web matrix had  $m_1=8$  prey,  $n_1=6$  predators, and  $A_1=19.2$  predator-prey couples (neglecting the requirement that  $A_1$  be integer for the sake of argument). Then its (average predators per prey)<sub>1</sub> is 2.4 and its (average prey per predator)<sub>1</sub> is 3.2. Suppose the second food web matrix had  $m_2=4$ ,  $n_2=10$ , and  $A_2=16$ . Then its (average predators per prey)<sub>2</sub>=4.0 and (average prey per predator)<sub>2</sub>=1.6. Then the grand mean over both food webs of the average predators per prey is 3.2 and the grand mean of the average prey per predator is 2.4, which are close enough to the observed. But the straight line through the pairs  $(n, m)$  satisfies  $m=14-n$ . Only because nature assures a constant proportion of prey to predators do the grand mean of the average predators per prey and the grand mean of the average prey per predator apply to all food webs.

If the ratio of prey to predators in community food webs is a constant of the order of 3/4, then dividing equation (3) by  $n$  leads to the prediction that a regression (Fig. 2) of average prey per predator against average predators per prey should be a straight line through the origin with slope 3/4. The regression coefficient of a straight line through the origin is 0.69, not far from 3/4.

Fig. 2 The average number of kinds of prey per kind of predator and the average number of kinds of predators per kind of prey in community food web versions.

In conclusion, in community food webs, the number of kinds of prey, as operationally defined by field ecologists, approximates 3/4 the number of kinds of predators. This results from the study only of an ensemble of food webs, rather than of individual cases.

## Inhibition of drinking by intrahypothalamic administration of morphine

MORPHINE inhibits the release of acetylcholine (ACh) within both the peripheral<sup>1–4</sup> and central<sup>5–9</sup> nervous systems. This would suggest that a major effect of acute morphine treatment should be inhibition of behaviour mediated by central cholinergic transmission, but few behavioural demonstrations of this antagonism exist. We report here that intrahypothalamic injections of equimolar concentrations of morphine effectively antagonise the muscarinic-cholinergic drinking response<sup>10–13</sup> elicited by injection of 4.0 nmol of carbachol into the hypothalamus. In addition, intracranial (i.c.) injections of morphine also blocked drinking elicited by several other dipsogenic stimuli, while not affecting eating. The results suggest that morphine not only inhibits the release of ACh but also may block the postsynaptic muscarinic receptor. This inhibitory effect of i.c. morphine may, furthermore, provide a simple behavioural screening test for central opiate activity.

The effects of intrahypothalamic applications of morphine on water consumption were investigated in two experiments involving 44 adult male Sprague-Dawley rats. In each experiment, stainless steel cannulae (24 gauge) were stereotactically implanted into the perifornical hypothalamus<sup>14</sup> (PFH) of anaesthetised (Nembutal, 40 mg per kg body weight intraperitoneally) rats. Each subject was allowed at least one week to recover from surgery before testing was initiated. Drugs were administered i.c. as free bases in 1- $\mu$ l volumes through a 31-gauge hypodermic needle directly connected to a 50- $\mu$ l syringe. A repeating dispenser (Hamilton, PB600–1) was used to ensure reliability of injection volumes. Before any tests of morphine, stable baseline drinking to the dipsogenic stimuli was ensured across several days of testing. Ground rat chow and water intake were measured after 1-h periods of both control and experimental treatment conditions. Tests of drug antagonism were conducted by administering an equimolar dose of the antagonist to the same brain area 5 min before the injection of the agonist.

In the first experiment, 28 rats were randomly divided into three groups. Eating and drinking were assessed in each group after the control injection of saline and the subsequent application of carbachol (Fig. 1). As previously reported<sup>12</sup>, carbachol elicited significantly more eating ( $F(1,25) = 15.35$ ,  $P < 0.01$ ) and drinking ( $F(1,25) = 67.72$ ,  $P < 0.01$ ) than the control manipulation.

On the following day, the antagonistic effect of morphine on carbachol-elicited drinking was investigated. The reversibility of morphine antagonism of drinking was also tested in another group by the i.c. injection of the narcotic antagonist, naloxone, 5 min before the morphine treatment. Although there were no significant differences in food intake between the three groups (Table 1), there was a significant overall effect on water consumption ( $F(2,25) = 13.17$ ,  $P < 0.01$ ). Post hoc *t* tests indicated no difference in drinking between the saline pretreated carbachol (SSC) and naloxone-morphine pretreated carbachol (NMC) groups, while each of these groups differed from the saline-morphine pretreated carbachol (SMC) group ( $P < 0.01$ ). Thus, i.c. morphine blocked carbachol-elicited drinking, while not significantly affecting eating. Furthermore, this antagonism of drinking was reversed by pretreatment with naloxone.

Since cholinergic influences have also been implicated in the mediation of deprivation-induced drinking<sup>13</sup>, 18 of the above rats were deprived of food and water for 24 h and tested for

Fig. 1 Mean food (a) and water (b) intake ( $\pm$  s.e.m.) by rats during the 1-h following the injection of carbachol (4.0 nmol) and the preceding control injection of 1  $\mu$ l of normal saline (stippled area). This test was conducted after the rats had received three previous daily injections of carbachol and saline and represents the animals' response during the fourth trial. Group designations refer to the morphine test, which was conducted on the following day: S, saline; C, carbachol; N, naloxone; M, morphine. Numbers in parentheses are number of animals tested.

morphine antagonism of drinking and eating. That i.c. morphine effectively antagonised drinking while not significantly affecting eating (Table 2) indicates that this adipsic effect is not due to nonspecific depression of behaviour.

In the second experiment, 16 experimentally-naïve rats were randomly assigned to two groups to assess the effect of i.c. morphine across several other paradigms of drinking. Since morphine has been reported to inhibit the uptake of carbachol into brain slices<sup>15</sup>, carbachol was administered before morphine in the first test. Although carbachol was injected well before morphine and undoubtedly had been taken up by central neurones (as shown by a normal drinking latency of 5 min), drinking was still significantly reduced by the opiate (Table 3). The second test examined the effects of i.c. morphine treatment on drinking elicited by hypertonic saline<sup>13</sup>. Again i.c. morphine effectively obviated the drinking response to this dipsogenic challenge (Table 3). Pretreatment with equimolar doses of morphine also antagonised drinking elicited by the potent dipsogenic peptide, angiotensin II<sup>16</sup> (Table 3).

To provide additional control for nonspecific effects of morphine on consummatory behaviour, two additional tests were conducted. Since morphine seemed to depress eating somewhat in previous experiments (Tables 1 and 2), the effects of

Table 1 Effects of intrahypothalamic morphine and naloxone pretreatments on carbachol-elicited eating and drinking

Group	N	Food intake (g per h)	P	Water intake (g per h)	P
SSC	10	1.1 $\pm$ 0.3	NS	12.0 $\pm$ 1.1	0.01
SMC	9	0.5 $\pm$ 0.3		2.7 $\pm$ 1.5	
NMC	9	0.6 $\pm$ 0.2		9.1 $\pm$ 1.7	

Mean food and water intake in grams ( $\pm$  s.e.m.) by rats during 1 h following the injection of carbachol (4.0 nmol). Group SSC received injections (1  $\mu$ l) of normal saline 10 and 5 min before carbachol, while groups SMC and NMC were injected with saline (1  $\mu$ l) followed by morphine (4.0 nmol) or naloxone (4.0 nmol) followed by morphine (4.0 nmol), respectively, 10 and 5 min before carbachol. Although there were no overall differences in food intake, group SMC drank significantly less water than group SSC or group NMC. There was no significant difference in water intake between groups SSC and NMC. Statistical inferences were made using analysis variance techniques with post hoc comparisons made by *t* tests. NS, not significant.

**Table 2** Effects of intrahypothalamic morphine treatment on eating and drinking elicited by 24 h food and water deprivation

Treatment	N	Food intake (g per h)	P	Water intake (g per h)	P
Saline	9	5.0±0.7	NS	6.2±0.8	0.01
Morphine	9	3.4±0.8		1.2±0.4	

Following the test of morphine inhibition of carbachol-elicited eating and drinking (Table 1), 18 rats were deprived of food and water for 24 h. The saline group received 1 µl of normal saline, while the morphine group was injected with 4.0 nmol of morphine 5 min before being presented with food and water. Intake in grams (±s.e.m.), was assessed during the 1-h period following the initial presentation of food and water. Although there was no difference between groups in food intake, morphine-treated animals drank significantly (*t* test) less water than did those given saline. NS, not significant.

i.c. morphine on eating and drinking elicited by 48-h food deprivation were investigated. It is well known that eating is reduced when drinking is severely inhibited. Therefore, the purpose of this test was to maintain hydration at near normal values with drinking being elicited by increased thirst subsequent to food consumption. As indicated in Table 3, there was no difference in food intake between the saline and morphine groups. Water intake, however, was still severely inhibited by the morphine treatment. To assess the effects of pretreatment with a non-addicting, non-analgesic stereoisomer, dextrophan was substituted for morphine in this final test. To control for the possibility of tolerance to the opiates, the groups were reversed with the dextrophan group never having been injected with opiates. In contrast to the previously-observed effects of morphine, i.c. dextrophan did not reduce either eating or drinking in these satiated rats (Table 3).

These experiments demonstrate a potent inhibitory effect of

**Table 3** Effects of intrahypothalamic opiates on eating and drinking elicited by various dipsogenic stimuli

S-C	8	1.1±0.4	NS	9.5±2.3	NS
D-C	8	1.6±0.3		11.0±1.9	

Mean food and water intake was measured in grams (±s.e.m.) during 1-h periods following various dipsogenic stimuli. During the first test, intracranial (i.c.) injections of carbachol (C; 4.0 nmol) were administered 10 min before the i.c. injection (1 µl) of saline (S) or 4.0 nmol morphine (M) with the rats being presented with food and water 5 min after the last injection. Six days later, i.c. M (4.0 nmol) or S (1 µl) was administered 5 min before the injection (2 ml; subcutaneously) by hypertonic (10%) saline (HS). After a 3-d latency, the antagonistic effects of i.c. M (4.0 nmol) or S (1 µl) were assessed when administered 5 min before i.c. angiotensin II (A; 4.0 nmol). Six days later, the rats were food-deprived (FD) for 48 h and presented with food and water 5 min after the injection (i.c.) of M (4.0 nmol) or S (1 µl). The last test, conducted 6 d later, assessed the effects of i.c. dextrophan (D; 4.0 nmol) and S (1 µl) as pretreatments (5 min) on eating and drinking elicited by 4.0 nmol (i.c.) C. Statistical significance is based on *t* tests. NS, not significant.

centrally-applied morphine across several paradigms of drinking. This effect was not due to nonspecific behavioural disruption, since the rats were alert and ate amounts of food comparable to the control groups. Furthermore, the antagonism of drinking seemed to be due to the narcotic properties of morphine, since it was reversed by pretreatment with naloxone. This hypothesis is strengthened by the lack of effect observed when the stereoisomer, dextrophan, was substituted for morphine.

These inhibitory effects of morphine on drinking are similar to results previously reported following administration of atropine or scopolamine and may reflect antimuscarinic cholinergic activity. Although pretreatments with atropine have been reported to block drinking elicited by carbachol<sup>11</sup>, hypertonic saline<sup>13</sup>, water deprivation<sup>13</sup>, and schedule-induced polydipsia<sup>17</sup>, atropine is apparently not nearly as potent as morphine in paradigms that do not involve exogenous cholinergic dipsogens. Furthermore, atropine has been reported to be ineffective against drinking elicited by angiotensin II<sup>18</sup>, while pretreatment with morphine effectively blocked this behaviour. A possible difference between the central nervous system activity of morphine and atropine may be the effect of these drugs on the release of ACh. Thus morphine, which has been extensively reported to inhibit the release of ACh, may exert its antagonism of drinking through both the inhibition of release and postsynaptic muscarinic blockade. Thus, drinking in paradigms not involving exogenous cholinergic dipsogens, such as water deprivation, are not as readily antagonised by atropine. Conversely, morphine will readily inhibit the release of ACh and thus block the cholinergic components of deprivation-induced drinking. The reduction of drinking following i.c. angiotensin by morphine pretreatment may furthermore reflect a cholinergic component in the mediation of this behaviour<sup>18</sup>.

Antimuscarinic cholinergic effects of morphine have been suggested by several observations. The muscarinic cholinergic agonist, pilocarpine, stimulates transmission in the superior cervical ganglion of the cat<sup>19</sup>, and this effect, furthermore, is blocked by atropine as well as by morphine<sup>19</sup>. The observation that muscarinic receptor blockers reduce symptoms of precipitated morphine withdrawal<sup>20</sup> also suggests antimuscarinic activity of morphine is provided by the observation that tolerance to epileptiform electroencephalogram patterns following microinjections of morphine into the amygdala is accompanied by cross tolerance to scopolamine<sup>21</sup>.

We are extending these investigations to other opiate and opioid drugs and investigating the effect of systemically-administered morphine on these various dipsogenic challenges. It is possible that these tests may lead to a simple behavioural test of central narcotic activity.

## EPR signals in chloroplasts responding to illumination sequence of four flashes

THE use of water as the electron donor and the consequent evolution of oxygen is one of the most important properties of photosynthesis by higher plants and algae. The properties of the enzyme systems involved in water oxidation are essentially unknown, however. Two new electron paramagnetic resonance (EPR) signals observed at low temperature in oxygen evolving chloroplasts are described here. The signals disappear and appear in response to short flash illumination, before freezing, of the chloroplasts, presumably due to changes in oxidation state of the components giving rise to the signals. The changes occur in response to a cycle of four flashes; it is suggested that they may reflect the oxidation states of the oxygen evolving system of the chloroplasts.

Manganese may be an important component of the oxygen evolving system<sup>1</sup>, but attempts to observe changes in the redox state of manganese associated with oxygen evolution have not been successful. Kinetic measurements<sup>2,3</sup> have shown that when chloroplasts are illuminated with short intense flashes of light, each of which causes only a single electron to be transported by each photosynthetic reaction centre, oxygen is evolved with a periodicity of four flashes. These experiments suggest that each water oxidising enzyme system accumulates four oxidising equivalents, one with each turnover of the photosystem II reaction centre, before reacting with water. This observation may be formalised in the 'S' state hypothesis of Kok *et al.*<sup>3</sup>

In kinetic experiments oxygen evolution normally shows a peak after the first three flashes, and then with a periodicity of four flashes, indicating that the distribution of the 'S' states is not random in the dark.  $S_1$  and  $S_0$  are thought to be most stable in the dark, with  $S_1$  predominating in most experiments<sup>4</sup>. The light induced progression between the 'S' states represents a change in redox state of the proposed enzyme, each step involving a single electron oxidation. As this enzyme may be expected to contain a transition metal ion complex it seems likely that these changes could be detected by EPR spectroscopy. Several studies of chloroplast electron transport using EPR and flash illumination have been reported but none has identified signals corresponding to the 'S' states<sup>5</sup>. Both optical and nuclear magnetic resonance (NMR) spectrometry have been used in attempts to identify the 'S' state components. Pulles *et al.*<sup>6</sup> and Mathis and Haveman<sup>7</sup> have reported optical changes at 310 nm responding to flash illumination with a periodicity of four. The chemical nature of the component involved is unknown. Wydrzynski *et al.*<sup>8,9</sup> observed changes in the relaxation rate of water protons showing response to flash illumination with a periodicity of four using NMR spectrometry: they presented evidence that their results are consistent with the participation of manganese in the flash-induced changes in the relaxation rate of water protons.

We have used flash illumination at room temperature followed by rapid freezing to 90 K in an attempt to trap the 'S' states, and low temperature (4.2–30 K) EPR spectrometry to detect new EPR signals showing a response to flash number, which would be expected from the oxygen evolving enzyme system, or a chloroplast component reflecting the redox state of this system.

Figure 1 shows the EPR spectra of a chloroplast preparation in the dark and after exposure to 0, 1, 2, 3, or 4, 20- $\mu$ s flashes from a 25-J xenon-arc lamp, the multiple flashes were spaced at 200-ms intervals. The samples were frozen within 1 s using an isopentane bath at 90 K and stored at 77 K until the spectra were recorded. The spectra show a signal in the dark at  $g = 3.09$ .

**Fig. 1** EPR spectra of broken spinach chloroplasts in the  $g = 3.0$  region. Broken chloroplasts were prepared in a Mn-free medium containing 1mM EDTA<sup>15,16</sup>. The chloroplasts which exhibited an uncoupled rate of oxygen evolution of 306  $\mu$ mol per mg chlorophyll per h were kept in the dark on ice for 0.5 h. The chlorophyll concentration was 1.55 mg ml<sup>-1</sup>. EPR spectra were recorded as described previously<sup>17,18</sup>. The conditions for each spectrum were as follows. Frequency 9.189 GHz, power 20 mW, modulation amplitude 1mT, scan rate 100 mT min<sup>-1</sup>, gain 500, temperature 10 K. The samples were illuminated with a, 0; b, 1; c, 2; d, 3 and e, 4 flashes. The spectra were recorded in the dark.

After one flash there is essentially no signal in the  $g = 3.0$  region. After a second flash a large signal appears centred at  $g = 2.79$ . The properties of this signal suggest that it arises from a different redox state to that giving rise to the dark signal. After the third flash there is again no signal while after the fourth flash, which in the 'S' scheme should regenerate the dark state, the original signal reappears at  $g = 3.07$ . This signal is, however, usually rather smaller than the initial dark signal.

These signals might be considered to correspond to the  $S_1$ ,  $S_2$ ,  $S_3$  and  $S_0$  states of Kok's model.  $S_4$  would not be seen as it reacts rapidly with water<sup>4</sup>. The rate of this reaction might, however, control the extent of regeneration of  $S_1$  by the fourth flash. Some decay of each stage will also occur between flashes, this and other problems well documented for the kinetic experiments will rapidly result in a loss of periodicity and the ability to detect the signals.

As described above, the response of these signals to flash illumination strongly suggests that they reflect the oxidation state of the water oxidising enzyme system. The EPR properties

of these signals are extremely unusual, however, making it experimentally very difficult to investigate the role of the components giving rise to them, or to attribute them to a specific chloroplast component. In all preparations in which we have observed these signals they show strong orientation effects, similar to those observed in EPR studies of single crystals<sup>10</sup>. Fig. 2 shows the effect of rotating a dark sample (*a* in Fig. 1) in the EPR cavity. If the sample is oriented to give maximal signal size ( $0^\circ$ ) and then rotated the signal disappears ( $40^\circ$ ) and then reappears ( $180^\circ$ ). At intermediate positions the signal size, linewidth and  $g$  value differ. Figure 2c ( $50^\circ$ ) shows this effect. We have found that in order to be sure that a sample does or does not have a signal the spectrum must be recorded every  $10^\circ$  through  $180^\circ$ , 18 spectra per sample. The spectra in Fig. 1 show the maximum signal size for 0, 1, 2, 3 and 4 flashes from a set of 18 spectra for each sample. The apparent  $g$  value also changes with orientation as is observed in a single crystal. The  $g$  value and linewidth of the dark signal is also temperature dependent. Figure 3 shows the temperature dependence of the dark signal. The signal has a higher  $g$  value at lower temperatures with  $g = 3.38$  at 3.8 K,  $g = 3.27$  at 11.7 K and  $g = 3.14$  at 19.8 K. The linewidth also changes with temperature becoming narrower at lower temperatures being 70 G at 3.8 K, 120 G at 11.7 K and 170 G at 19.8 K with the sample orientation used in Fig. 3. The temperature dependence of the  $g$  value of the dark signal suggests that the signal arises from a ferromagnetic complex. Ferromagnetism is most commonly observed with iron; however, several other transition metals, but not apparently

Fig. 2 Effect of sample position on the dark EPR signal in broken spinach chloroplasts. Sample and conditions as for Fig. 1a. The relative orientations of the samples were *a*,  $0^\circ$ ; *b*,  $180^\circ$ ; *c*,  $50^\circ$  and *d*,  $40^\circ$ .

Fig. 3 Effect of temperature on the dark EPR signal in broken spinach chloroplasts. Conditions and samples as in Fig. 1a except that the temperatures were *a*, 19.8 K; *b*, 11.7 K; *c*, 3.8 K.

manganese, can show this property<sup>11</sup>. Ferromagnetism is a co-operative effect seen only when two or more atoms are in close proximity. Oriented ferromagnetic EPR signals have been reported from nerve tissue and nucleic acid preparations<sup>12,13</sup>. These signals were observed at room temperature, however, unlike the signals reported here which could not be observed above 40 K. We have not observed any temperature dependence of the  $g$  value of the signal seen after two flashes, indicating that the redox state giving rise to this signal is not ferromagnetic and is therefore different from the state giving rise to the dark signal.

Although the properties of these signals are unusual, the results presented here have been obtained consistently mainly in spinach chloroplasts but also in lettuce and pea chloroplasts. They are not seen in chloroplasts which have been washed with Tris, (0.8 M Tris-HCl pH 8.0 for 10 min at  $2^\circ$ , the thylakoids were then centrifuged and resuspended in the original medium), a procedure which inactivates the water oxidation system<sup>14</sup>, or in photosystem I particles prepared with the anionic detergent Triton X-100. The association of these signals with chloroplasts and their absence from photosystem I particles, together with the observation that they are lost when the oxygen evolving system is destroyed, suggest that the signals are associated with photosystem II. EPR signals responding to single turnover flash illumination might be associated with either the electron donor or acceptor sides of photosystem II. But signals associated with the acceptor would be expected to show a binary, two flash, response cycle, as the acceptor is thought to be a quinone which would be fully reduced in two steps. Signals associated with the water-oxidising system would be expected to show a four-flash response cycle. The signals reported here apparently show a four flash cycle as two states with different signals and two states without signals are observed. These changes would correspond to a model of the oxygen-evolving complex in which the electrons are removed sequentially from a single complex. They would not fit models in which electrons are removed from isolated centres each of which undergoes the same redox reaction.

We conclude that these signals probably reflect the oxidation state of the water oxidising enzyme system; future experiments

should lead to the identification of the component giving rise to these signals and the properties of this component which lead to orientation of the signal.

This work was supported in part by the UK SRC and the University of London Research Fund. We thank Professors E. A. Bell and D. O. Hall for permission to use the EPR spectrometer at the Department of Plant Sciences, King's College, and to Dr D. Williams-Smith (Guy's Hospital Physics Department) for helpful discussion.

## Effects of foetal haemoglobin on susceptibility of red cells to *Plasmodium falciparum*

HIGH gene frequencies for the sickling disorders and  $\beta$  thalassaemia may be due to the relative protection against *Plasmodium falciparum* malaria which has been afforded to heterozygous carriers<sup>1</sup>. In sickling disorders the properties of the abnormal haemoglobin may be responsible for this phenomenon<sup>2-4</sup> but the red cells of adult  $\beta$  thalassaemia heterozygotes contain reduced amounts of normal haemoglobin<sup>5</sup> and are indistinguishable from normal red cells with respect to the rates of invasion and growth of *P. falciparum* (G.P., D.J.W. and R.J.M., in preparation). Hence it is not clear how the  $\beta$  thalassaemia polymorphism has been maintained. There is a possible explanation, however. At birth red cells contain mainly foetal haemoglobin (Hb F); adult haemoglobin (Hb A) replaces Hb F during the first year of life. The rate of decline of Hb F production during this period is retarded in infants heterozygous for  $\beta$  thalassaemia as compared with normal infants<sup>6</sup>. If the presence of Hb F were to protect red cells against *P. falciparum*,  $\beta$  thalassaemia carriers aged 6-18 months might be at an advantage when passive immunity to *P. falciparum* is waning but active immunity is not fully established and mortality from malaria is high<sup>7</sup>. To test this hypothesis we have compared the rates of invasion and growth of *P. falciparum* in red cells containing Hb A with those containing Hb F using a modification of the *in vitro* culture system<sup>8-10</sup>.

Samples of 5 ml of blood containing synchronous late ring stages of *P. falciparum* were collected into heparin (10 IU ml<sup>-1</sup>) and layered onto a 6 × 2 cm column of Whatman CF11 cellulose in phosphate-buffered saline (PBS). The

leukocyte-depleted red cells were washed through the column into 2-l Ehrlenmeyer flasks with 100 ml supplemented medium 199<sup>8</sup>. The flasks were gassed with 5% CO<sub>2</sub>-95% air and incubated at 37 °C with gentle shaking. After about 24 h, when the parasites had grown to the schizont stage, the red cells were recovered by centrifugation and reconstituted to the original 5 ml volume with medium 199. Plasmagel 2.5 ml (3% w/v gelatin; Bellon) was added and the cells were allowed to sediment for 15 min at 37 °C to concentrate the schizont-infected cells in the upper layer. The latter were then suspended in a mixture of 3 parts supplemented medium 199 and 1 part non-immune AB serum. The uninfected red cells which were to be examined for the rate of parasite invasion and growth were collected into heparin, washed three times in PBS, the buffy coat removed and added to an appropriate volume of the parasitised red cell suspension so that the final concentration was approximately 80 × 10<sup>3</sup> cells per  $\mu$ l with 2-5% schizont-infected cells. The mixture was plated into the wells of a microtissue culture plate (250  $\mu$ l per well) and incubated in 5% CO<sub>2</sub>-air at 37 °C without shaking. At various times blood films were made and either stained with Giemsa or treated by the acid-elution method<sup>11-13</sup> modified to demonstrate Hb F-containing cells while at the same time allowing adequate morphological characterisation of parasites.

*P. falciparum* preferentially invades young, metabolically active red cells<sup>14</sup>. As this study was designed to compare the rates of invasion and growth *in vitro* in cells containing Hb A with those containing Hb F, and as these cells might be of different metabolic ages, a preliminary series of experiments was carried out to examine the effect of cell age on the rates of invasion and growth of *P. falciparum* in the *in vitro* system. Normal red cells were fractionated by age<sup>15,16</sup> and each fraction was mixed separately with infected cells. In each case the rate of invasion of the younger red cell population was significantly greater than that of the

Table 1 Invasion and development of *P. falciparum* in normal red cells of different ages

Cell fraction	Reticulocytes (%)	Invasion Parasites (%)	Developmental stages of 100 parasites per cell fraction							
			R		S		L		G	
			S	L	S	L	S	L	S	L
Whole blood	0.4	5.0	0	3	40	30	11	1	2	13
Top	2.5	7.9	0	2	39	32	11	2	1	13
Middle	0.6	3.6	0	4	36	29	14	3	0	14
Bottom	0.2	3.3	0	3	36	24	16	1	2	18
Whole blood	2.4	5.1	0	1	31	37	14	1	1	15
Top	9.6	8.9	0	3	40	26	10	2	0	19
Middle	1.5	4.5	0	2	42	24	10	2	0	20
Bottom	0.1	3.2	0	0	49	21	10	1	0	19

Uninfected adult red cells were centrifuged at 2,500g for 1 h at 4 °C. Fractions of approximately 0.2 ml were removed from the top, middle and bottom of the column of red cells and from whole blood. Reticulocyte counts were done to confirm separation on the basis of age. Suspensions of schizont-infected cells were added to each fraction and the mixtures were incubated as described in the text. The percentage of ring forms in each fraction arising from a fixed inoculum of schizonts is shown for two experiments. At least 1,000 red cells were examined from each fraction. In each case a  $\chi^2$  test showed a significantly greater percentage of parasites in the top (young) cell as compared with the bottom fraction ( $P < 0.01$ ). To assess parasite development smears were made after 53 h in culture and the maturity of parasites in 100 singly infected cells in each fraction was assessed. Rings (R) were forms without pigment, trophozoites (T) had a single clump of pigment and a single nucleus, schizonts (S) had more than one nucleus, gametocytes (G) had diffuse pigment, and abnormal forms (A) were those in which there was no nuclear-cytoplasmic differentiation on staining and which were pyknotic. The rings, trophozoites and schizonts were further subdivided into small (S) and large (L) forms. There was no significant difference in the pattern of development of the parasites between the various cell fractions.

older cells (Table 1). The further growth and development of the parasites in the different aged cell populations were assessed both by morphological examination (Table 1) and  $^3\text{H}$ -isoleucine incorporation<sup>17,18</sup>. Parasite growth assessed by either method was similar in each cell fraction. Thus in this *in vitro* system the parasites preferentially invade young metabolically active cells but there is virtually no difference in the rates of development in red cells of differing ages.

To determine whether Hb F has any effect on invasion of red cells by *P. falciparum*, the relative rates of invasion of Hb A and Hb F-containing cells were compared. Hb A-containing cells were obtained from normal adults. Hb F-containing cells were derived from four sources—normal newborn infants, infants aged 3–6 months, homozygotes for the British type of hereditary persistence of foetal haemoglobin (HPFH)<sup>19</sup> and heterozygotes for the African form of HPFH<sup>20</sup>. The choice of these Hb F-containing cells was based on the following rationale. The red cells of newborn infants contain mainly Hb F and are metabolically younger than those of normal adults<sup>21</sup>; by making an artificial mixture of newborn-infant and adult cells it would be possible to compare the rates of invasion of two red cell populations of different metabolic ages with Hb F in the 'younger' cells. In the blood of infants aged 3–6 months Hb F production has almost ceased and the newly-produced red cells contain almost entirely Hb A; in the same blood sample it would be possible to examine the relative rates of invasion of Hb A and Hb F-containing cells, in this case the latter being the metabolically older population. The red cells of homozygotes for the British form of HPFH contain increased amounts of Hb F which is unevenly distributed, some cells carrying mainly Hb F and others mainly Hb A<sup>18</sup>. Since the metabolic ages of these populations are similar it would be possible to study the relative invasion rates of Hb F and Hb A-containing cell populations of the same metabolic age in the same blood sample. The red cells in the African form of HPFH, apart from their increased levels of Hb F, are similar in

every way to those of normal adults<sup>19</sup>. The results are summarised in Table 2. In the mixture of newborn and adult red cells the Hb F-containing cells were preferentially invaded, in the red cells of the 3–6-month old infants there were significantly more parasites in the Hb A-containing cells, and in the red cells of the British HPFH homozygotes the Hb F and Hb A-containing populations were equally invaded. The rates of invasion of the African HPFH cells were identical to those of normal adult cells in parallel cultures. These experiments show that Hb F has no direct effect on the rate of invasion of red cells by *P. falciparum* and provide further evidence that invasion is a cell-age related process.

**Table 3** Development of *P. falciparum* in cells containing varying amounts of foetal haemoglobin

	F	28	34	28	4	0	0	0	6

Experimental methods are described in the text and the designation of cell type and the development stages of the parasites are the same as those in Table 1. All cells were cultured in the same wells except for the African HPFH and Hb A-containing control cells which were in parallel. There is a significant retardation of development of parasites in the Hb F-containing cells in each case.

A further series of experiments was carried out to compare the development of *P. falciparum* in Hb F-containing cells with that in cells which contain mainly Hb A. In addition to the cells used in the experiments described above a mixture of normal adult cells and cells from a compound  $\beta^0/\delta\beta$  thalassaemia heterozygote which contain almost 100% Hb F<sup>22</sup> were studied. The cells were infected *in vitro* and at various times smears were made from the cultures and a comparison of the maturity of parasites in the Hb A and Hb F-containing cells was made. The results of representative experiments are summarised in Table 3. There was a significant reduction in the number of mature forms of *P. falciparum* in the Hb F-containing cells regardless of their source or age. Hence the presence of Hb F in red cells causes retardation of growth of *P. falciparum* *in vitro*. Since it was observed in red cells containing Hb F obtained from both infants and adults with several different genetic conditions, this phenomenon is probably related to

**Table 2** Invasion by *P. falciparum* of red cells containing varying amounts of foetal haemoglobin

Cell type	Adult+cord		Source of Hb F-containing cells				Infant

Experimental conditions as described in the text. Where Hb A and Hb F-containing cells were present in the same culture, smears were stained by a modification of the acid elution technique to distinguish between the following groups of cells:— those containing predominantly Hb A where the haemoglobin was completely eluted (A), cells containing Hbs A and F (intermediate or I cells) and cells containing mainly Hb F (F cells)<sup>13</sup>. Since the mixture of adult and cord cells was artificial the group of I cells has been omitted. The African HPFH and adult control cells were grown in parallel and not in the same wells, as the acid elution technique does not readily distinguish African HPFH cells from those containing Hb A in an artificial mixture. In these cases the intermediate (I) group is omitted. At least 2,000 cells were counted in each experiment. The difference in parasitisation of the A and F cells in the adult/cord and infant cell experiments was significant at the 1% level. There was no significant difference between the parasite counts in the A and F populations in the British or African HPFH red cells.

the presence of Hb F and not to other metabolic properties of the red cells. Further evidence that this is the case was obtained in those experiments in which it was possible to define red cells which contained intermediate amounts of Hb F (Table 3). The degree of retardation of growth of *P. falciparum* in these cells was approximately intermediate between that in cells which contained predominantly Hb A or Hb F suggesting that the degree of retardation of growth of the parasite is broadly correlated with the level of Hb F in the red cell. Since the phenomenon was observed in the red cells of the African HPFH heterozygote, it seems likely that growth retardation can result from as little as 7 pg Hb F per cell.

Whether Hb F causes relative retardation of growth and development of *P. falciparum* by its high oxygen affinity, different primary structure from that of Hb A, or by another mechanism, remains to be determined. Whatever the mechanism this phenomenon, taken together with the retardation of the rate of decline of Hb F production over the first year of life in infants heterozygous for  $\beta$  thalassaemia, offers a possible mechanism for the maintenance of the  $\beta$  thalassaemia polymorphism. Any property of the red cell which causes even minor growth retardation or interferes with synchronisation of development of the parasite might provide some degree of protection, particularly at a stage of development when passive immunity is waning and active immunity is not established. Further data on the levels of Hb F which are required for protection, and on the intracellular levels of Hb F in such heterozygous infants during their first year is required to test this hypothesis. Its particular attraction is that because the rate of decline of Hb F is retarded in infants with  $\beta$  chain structural haemoglobin variants as well as those with  $\beta$  thalassaemia<sup>8</sup>, it provides a unifying mechanism for the high gene frequencies of the  $\beta$ -chain haemoglobinopathies. It does not, of course, exclude the operation of other protective mechanisms such as have been proposed for cells containing Hb S<sup>9-11</sup>.

## Further link between complement activation and blood coagulation

EVIDENCE for interactions between the complement and haemostatic systems has come from two lines of research—blood platelets have been shown to interact with various complement components<sup>1-6</sup>, and more ambiguous results have been obtained with respect to the role of complement in endotoxin shock and the Schwartzman reaction<sup>7-13</sup>. We report here that the activated complement component C3b triggers a marked increase of tissue thromboplastin (factor III) activity in cultured human monocytes. Differential counting and non-specific esterase staining<sup>14</sup> of the final preparations regularly revealed more than 85% monocytes.

After isolation and incubation as described in Table 1, the cells were rinsed 10 times with sterile saline and mechanically displaced with a rubber policeman into 1 ml of Veronal-buffered saline<sup>15</sup>. Tissue thromboplastin activity was tested as before<sup>16</sup>. Procoagulant activity required the presence of coagulation factor VII and was inactivated rapidly by phospholipase C<sup>17</sup> and by a monospecific antiserum against tissue thromboplastin<sup>18,19</sup>. The procoagulant was thus identified as tissue thromboplastin. Guinea pig complement factor C3b was generated and purified as described by Nicholson *et al.*<sup>20</sup>.

Table 1 summarises data from five experiments. C3b gives a marked increase in tissue thromboplastin activity of isolated monocytes cultured in the presence or absence of serum. This increase was of the same order of magnitude as that seen after endotoxin addition (data not shown). Cycloheximide (Sigma) (final concentration 10-20  $\mu$ g ml<sup>-1</sup>) inhibited the increase completely; thus protein synthesis was probably required. The effect of C3b was significant even at the lowest concentration

Table 1 Effect of C3b on tissue thromboplastin activity of human monocytes

Experiment	Additions ( $\mu$ g ml <sup>-1</sup> )	Serum (20%)	Activity (units per mg protein)	Increase* (%)
1	C3b (0.5)	+	41.7	256
	C3b (0.5) + cycloheximide (20)	+	11.7	0
	None (control)	+	11.7	
2	C3b (12.5)	+	37.0	348
	C3b (12.5)	-	18.7	127
	None (control)	+	8.2	
3	C3b (15)	+	20.6	131
	C3b (30)	+	25.7	189
	None (control)	+	8.9	
4	C3b (30)	-	15.5	78
	None (control)	-	8.7	
5	C3b (30) + endotoxin (50)	+	69.3	1,055
	C3b (30)	+	56.6	843
	None (control)	+	6.0	

Human monocytes were isolated from mixed buffy coats by a modification of the Bøyum method<sup>21</sup> including dextran sedimentation, two Ficoll-Paque (Pharmacia), gradients and several differential centrifugations. The cells adhering to the Petri dishes (Nunc), were selected by washing away non-adherent cells. Incubations lasted for 5 h. A standard preparation of human brain thromboplastin that clotted normal citrated plasma in 13 s was taken to contain 100 units ml<sup>-1</sup> and dilutions of this preparation were used to establish a standard curve. Protein was determined by the Lowry method<sup>22</sup>. The endotoxin was *Escherichia coli* 055:135 type B (Difco). Each value is the mean of determinations in triplicate on duplicate cultures. The test samples had protein concentrations of 117-726  $\mu$ g ml<sup>-1</sup> and the actual clotting times recorded were 18.7-38.8 s in C3b-stimulated samples and 41.3-68.8 s in controls. The clotting times were converted to thromboplastin units by means of the standard curve and normalised to units per mg protein.

\*Control values subtracted.

tested ( $0.5 \mu\text{g ml}^{-1}$ ). The apparent lack of a dose-response relationship is caused by the varying magnitude of the response of the different cell preparations used in the various experiments. In experiment 3 (Table 1) where different aliquots of the same cell preparation were exposed to two different levels of C3b, the higher dose gave the higher response. Unstimulated monocytes cultured for 5 h had very low activities (Table 1). C3b alone did not influence the assay system (tested up to  $30 \mu\text{g ml}^{-1}$ ).

Isolated monocytes develop increased procoagulant activity when stimulated by endotoxin<sup>23</sup>. This phenomenon probably requires both mRNA and protein synthesis (H.P. and A.C.A., in preparation) and is seen in monocyte cultures virtually free from blood platelets. Granulocytes and non-adherent mononuclear cells are essentially unresponsive (data not shown).

Human monocytes and other macrophages have receptors for C3b<sup>24,25</sup>, and C3b is known to induce release of lysosomal enzymes from macrophages<sup>26</sup>. The production of C3 by normal macrophages<sup>27</sup> makes possible a positive feedback cycle<sup>28</sup>. This link between complement activation and the extrinsic blood coagulation system has pathogenetic implications in the initiation of disseminated intravascular coagulation and possibly of thrombosis, which are under study.

## Induction of autophagy by amino-acid deprivation in perfused rat liver

AUTOPHAGOCYTOSIS is generally regarded as an important mechanism for ridding the cell of injured or unwanted cytoplasmic constituents and for degrading normal components in response to energy needs<sup>1,2</sup>. Autophagy has been noted in HeLa cells deprived of foetal calf serum and amino acids<sup>3</sup>. It

has also been seen in rat liver after glucagon administration<sup>4,5</sup>, during nutritional deprivation<sup>7,8</sup> and in diabetes<sup>9,10</sup>. Thus autophagy could have a physiological role in the maintenance of body amino acid pools, although there is no direct experimental evidence for this. We reported previously that rates of proteolysis, and lysosomal sizes are seen to increase when rat livers are cyclically perfused with an unsupplemented medium and decrease in response to added amino acids<sup>11-13</sup>. We strongly suspected that autophagy was the underlying event, but the nature of the process has been difficult to define<sup>12</sup>. The possibility was considered that its expression was self-limited by the accumulation of amino acids from endogenous proteo-

**Fig. 1** Electron micrograph of a portion of a hepatocyte, adjacent to two bile capillaries (bc), from a liver perfused in the single-pass mode for 40 min with medium not supplemented with amino acids. After perfusion, livers were flushed with 10 ml of cooled perfusate plasma followed by 40 ml (in 4 min) of Karnovsky's glutaraldehyde-paraformaldehyde fixative<sup>2</sup>, diluted 1:7 with 0.1 M sodium cacodylate (pH 7.2); 1-mm cubes then were cut from the major lobes and fixation continued with full-strength Karnovsky's medium for 3-4 h in an ice bath; the tissues were post-fixed in 1.33% osmium tetroxide, buffered with s-collidine (pH 7.4) for 2 h at ice temperature. The blocks were imbedded in epoxy resin (Durcupan ACM, Fluka) and thin sections cut with a Sorvall Porter-Blum MT 2-B ultramicrotome from an area containing predominantly mid-zonal cells<sup>25</sup>. The sections were double-stained with uranyl acetate and either lead citrate or lead hydroxide before examination with an RCA-EMU-IV electron microscope. Numerous autophagic vacuoles are evident (arrows). Smooth endoplasmic reticulum, glycogen, a mitochondrion, and a portion of rough endoplasmic reticulum are especially well preserved within the vacuoles. Several of the autophagic vacuoles are limited by a double membrane throughout a significant portion of their circumference. In general, the hepatocytes seem to be in good condition. Mitochondrial swelling is not evident nor are there any large cytoplasmic vacuoles. There is some vesiculation which probably represents enlarged elements of the Golgi complex and which may play a part in the autophagic process.

lysis. We now show that when this accumulation is prevented by perfusing livers in the single-pass mode, autophagic changes appear that are morphologically indistinguishable from those occurring after maximal doses of glucagon<sup>4-6</sup>.

Livers from fed male rats of the Lewis strain (Microbiological Associates), weighing 120–150 g, were perfused *in situ* with a medium consisting of freshly washed bovine or sheep red cells suspended in Krebs–Ringer bicarbonate buffer (0.27 v/v) containing 3% bovine plasma albumin (Pentex) and 10 mM glucose. Amino acid levels in the perfusate plasma were reduced to 2.5% of normal rat plasma values as determined by direct analysis<sup>14</sup>. Perfusions were carried out as described previously<sup>15</sup> except that in all single-pass runs the outflow from the livers was not returned to the perfusion flasks<sup>16</sup>.

Perfusion of livers in the single-pass mode with a medium depleted of amino acids evoked a striking increase in autophagy (Figs 1 and 2) that attained maximal intensity by 20 min and was clearly evident as early as 5 min (data not shown). Although autophagic vacuoles were widely scattered throughout the cell, they were more numerous in the vicinity of Golgi vesicles. The variety of identifiable cytoplasmic inclusions was fairly typical of the contents of glucagon-induced vacuoles<sup>17</sup>. The one exception was glycogen; while it was a frequent lysosomal constituent in our experiments, it has not been noted consistently in glucagon studies<sup>4-6,17</sup>. This difference undoubtedly reflects the glycogen content of the cell at the time autophagy was underway. In most of these reports, the animals were starved and residual glycogen was undoubtedly lost through the glycogenolytic action of glucagon (through cyclic AMP). Although amino acid deficiency *per se* does not, in our experience, enhance glycogenolysis, we, nevertheless, considered the possibility that the albumin used in the medium might have carried substances capable of stimulating adenyl cyclase and autophagy. Analysis of tissue samples showed that cyclic AMP was not elevated, however (Table 1).

Effects of amino acid deficiency on the fractional cytoplasmic volumes of typical autophagic vacuoles are given in Fig. 2. With maximal deprivation, the fractional volume of autophagic vacuoles, 1.6%, was considerably larger than peak values after glucagon<sup>18</sup>, but compared closely with estimates after diabetes<sup>19</sup> and in neonatal rat livers at the time of maximal autophagy<sup>18</sup>. In other respects, however, our findings are similar to those seen with glucagon. The cross-sectional dimensions of lysosomal profiles, which were up to 1.8  $\mu$ m (Fig. 3), are in basic agreement with the data of Deter *et al.*<sup>5</sup>—we also noted, as they did, a significant decrease in the fractional volume of typical dense bodies (shaded fraction, Fig. 2). The addition of a 10 $\times$  physiological mixture of amino acids during single-pass perfusions completely prevented this autophagic increase and even reduced values below those in unperfused liver (Fig. 2). When the amino acids were added after autophagy was fully manifest (20 min), the vacuoles regressed almost completely with a half-time of 8–9 min (data not shown). This agrees closely with the time required to reverse the enhancement of lysosomal osmotic sensitivity in the perfused rat liver ( $t_{1/2}$  ~ 8 min)<sup>19</sup>, and as a first approximation, suggests that the fractional turnover rate for mixed autophagic vacuole contents is of the order of 0.08 per min.

During cyclic liver perfusion, most amino acids quickly attain steady-state levels that are about the same or only slightly lower than normal plasma values, and a few (including leucine, isoleucine, valine, glutamic acid and glycine) continue to rise<sup>13</sup>. But, as there is no external supply to replace those that are metabolised, a moderate deficiency does in fact exist and extra amino acids are provided by a significant increase in the rate of cytoplasmic proteolysis. It is evident from Figs 2 and 3 that autophagy and lysosomal enlargement increase in these conditions although to a smaller extent than was observed after more stringent deprivation. Our previous failure to demonstrate typical autophagic alterations during cyclic perfusion<sup>12</sup> can probably be explained by the technique of fixation used. In subsequent work we have shown it to be

Fig. 2 Fractional cytoplasmic volume of components of the lysosomal-vacuolar system. The following experimental conditions were evaluated: (1), no perfusion; (2), cyclic perfusion for 60 min with no additions of glucose or amino-acids; (3), single-pass perfusion for 40 min with 10 mM glucose but no added amino acids (the offset dashed line represents values obtained from livers perfused 20 min in the same conditions); and (4), single-pass perfusion for 40 min with a medium supplemented with amino acids at a concentration 10 $\times$  normal plasma levels and 10 mM glucose. The components of the lysosomal-vacuolar system have been divided into four groups. Each bar represents mean  $\pm$  s.e.m., of hepatic cytoplasm that is occupied by the designated component. The organelles classically described as autophagic vacuoles<sup>4-6</sup> appear above the horizontal axis. These autophagic vacuoles have been divided into two types: type B contains only elements of smooth endoplasmic reticulum,  $\pm$  glycogen; the remainder were classified as type C. A significant proportion of the inclusions within type C were recognisable mitochondria, rough endoplasmic reticulum, or free ribosomes. In addition, type C vacuoles contained unrecognisable membrane remnants and amorphous material which were probably cytoplasmic constituents in various stages of intralysosomal digestion. The remainder of the lysosomal elements, which comprised the population of 'dense bodies' are shown below the horizontal axis of the graph. Many of these elements seemed identical to peribiliary dense bodies generally observed in normal liver tissue<sup>26,27</sup> (shaded area). Profiles were also observed which had some region of electron-dense material but also contained an area of granularity indicating the presence of glycogen. These profiles were designated type A autophagic vacuoles. Electron micrographs were analysed by the point-counting method<sup>28</sup> which involved a test grid of intersecting lines. The method of stratified random sampling<sup>29</sup> was used in selecting blocks of tissue from the two major lobes of the liver. Four to six micrographs were examined from each block of tissue. The number of livers in each experimental group is shown in parentheses. For comparison with fractional volumes expressed as % of whole liver volume, the values in this graph may be multiplied by 0.771, the fractional volume of hepatic cytoplasm with respect to the whole liver<sup>30</sup>.

less effective than the present method in preserving intralysosomal fine structure.

As shown in Fig. 2, lysosomal elements which contained no distinct membrane remnants were divided into two subgroups according to whether they (1) exhibited the usual electron opacity of dense bodies (shaded), or (2), contained additional sharply demarcated zones of electron lucency type A.

Table 1 Liver cyclic AMP levels

Experimental condition	Liver cyclic AMP (nmol per g liver)
Unperfused (9)	0.812±0.080
Perfused (8) no amino acids	0.973±0.184
Perfused (7) 10× amino acids	0.917±0.171

Liver perfusions were carried out in the single-pass mode for 40 min with or without amino-acids, as described in the text and in Fig. 2 legend. Value are means±s.e.m. The number of livers from each group is given in parentheses. Livers were rapidly frozen using Wollenberger clamps previously cooled in liquid nitrogen. Total cyclic AMP was determined using either the protein binding assay of Gilman<sup>31</sup> as modified by Fain *et al.*<sup>32</sup> or the procedure of Steiner *et al.*<sup>33</sup>.

In all instances, the lucent areas displayed the characteristic granulation pattern of glycogen; these bodies are presumed to be autophagic vacuoles containing glycogen and probably some associated cytoplasmic matrix and smooth endoplasmic reticulum. It is evident from Fig. 2 that the fractional cytoplasmic volume of type A lysosomes tended to increase with amino acid deprivation. It is also apparent from Fig. 2 that the composition of cytoplasmic elements within the larger, more typical vacuoles was not the same in the four conditions

studied. The proportion of large forms containing mitochondria and/or fragments of rough endoplasmic reticulum (type C) increased relative to the total autophagic fractional volumes (types B+C) as the level of autophagy increased. Thus sequestration does not seem to be a random process, but exhibits some selectivity according to the degree of amino-acid deprivation.

The effect of amino acid depletion on the sequestration of cytoplasmic constituents by the lysosomal-vacuolar system is seen at normal levels of cyclic AMP and suggests that hepatic autophagy is controlled by amino acids independently of tissue alterations of the cyclic nucleotide. Insulin may also suppress this process<sup>12</sup>, but it is clear that maximal inhibition can be obtained by amino acids alone. In view of the magnitude of this autophagic response, it probably could account for most or all of the increase in protein degradation that occurs with amino acid lack. Taking 0.08 per min as a minimal estimate of the fractional rate of turnover of cytoplasmic components (and of protein) within autophagic vacuoles, we have computed that the rate of cytoplasmic processing by type B and C autophagic vacuoles would be 6.0% per h per liver under stringent amino acid deprivation, 2.2% per h with moderate deprivation (cyclic perfusion), and 0.2% per h with no deprivation (amino acid additions). The difference between the last two estimates, 2.0% per h, is capable of accounting for the increase in hepatic proteolysis that occurs in the absence of added amino acids during cyclic perfusion<sup>12,13</sup>. Since the number of autophagic vacuoles in rat liver had been shown to rise sharply in the postabsorptive period<sup>7</sup>, autophagy could explain much of the loss of total liver protein during this period<sup>20</sup>. The same process might also account for the enhanced proteolysis observed in cultured eukaryotic cells during nutritional deprivation or in the absence of macromolecular growth substances<sup>21,23</sup>.

We thank Drs Bryce L. Munger of the Milton S. Hershey Medical Center and John N. Fain of Brown University for laboratory facilities. This study was supported by US PHS grant AM-16356.

Fig. 3. Cumulative size distribution of dense bodies and autophagic elements (type A, B, and C). The data were compiled from measurements on the micrographs of Fig. 2, and the number on each curve corresponds to the experimental group as described in Fig. 2. Size estimates were obtained by directly measuring the maximum cross-sectional dimensions of profiles on electron micrographs. Dimensions were standardised by correcting for differences in magnification. Dense bodies and autophagic vacuoles were then arranged in size categories to the nearest 0.05  $\mu\text{m}$ . A total of 300 profiles were measured in group 2, 500 in group 3, and 200 in group 4.

## Monocular astigmatism effects on kitten visual cortex development

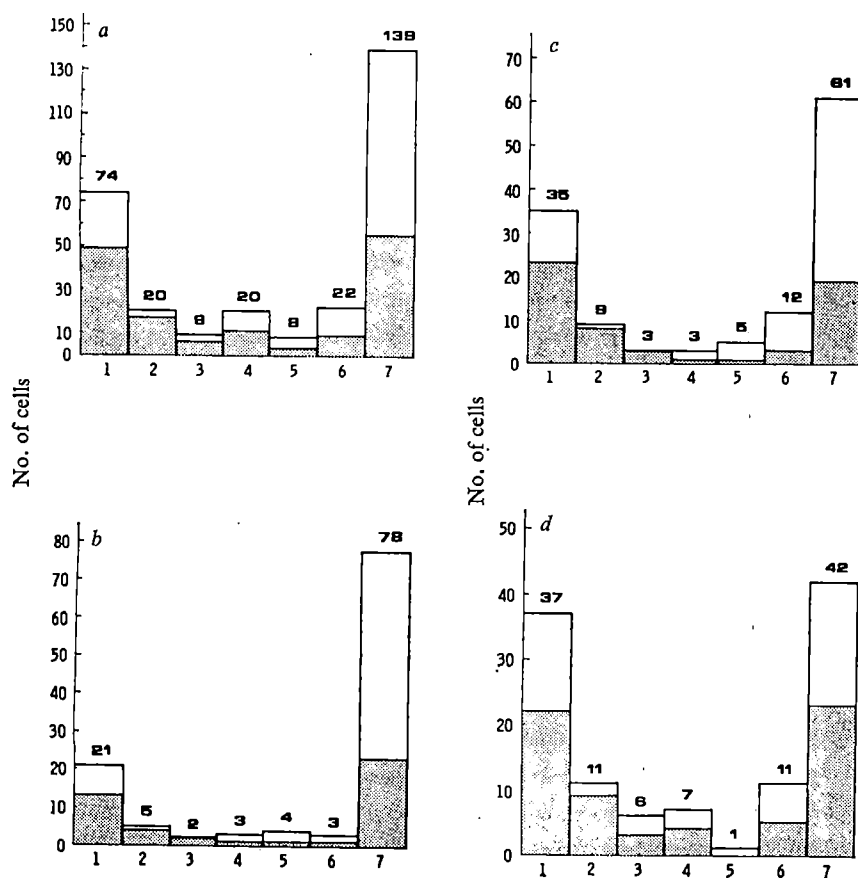

SIMULTANEOUS binocular vision during postnatal development is necessary for the maintenance of normal binocular connectivity in the kitten visual cortex. If one eyelid of a kitten is sutured shut throughout early development, three major changes can be observed when the eyelid is opened: (1) cortical cells lose functional connections with the deprived eye and may be activated only by the eye which remained open<sup>1,2</sup>; (2) cells in the layer of the lateral geniculate nucleus connected to the deprived eye shrink relative to those cells receiving innervation from the normal eye<sup>3,4</sup>; and (3) tested through its deprived eye, the cat seems to be almost totally blind<sup>5</sup>. We report here investigations on kittens which had been reared in the dark and then given visual exposure wearing goggles. One eye was allowed to view normally and the other looked through a cylindrical lens simulating astigmatism.

The behavioural, physiological and anatomical astigmatism changes which occur in the cat visual system after monocular deprivation are a result of competition between the two eyes, rather than a simple consequence of disuse<sup>6-9</sup>. Debate now centres on the mechanism of this competition. The two principle hypotheses, as put forward by Guillery<sup>6</sup> and discussed by others<sup>7-9</sup> are first, that cellular changes in the lateral geniculate body are a secondary consequence of a competitive interaction among geniculate terminals at the visual cortex. Here the primary event is the loss of functional connections with the cortical cell. Second, an intrageniculate competition mediated through inhibition between the layers of the geniculate results in a shrinkage of cells connected to the deprived eye. The loss of functional connections with the cortical units is considered to be a secondary consequence of the intrageniculate competition. We have dissociated these hypotheses by rearing kittens with

one eye viewing through a negative (axis vertical) 12-dioptre cylindrical lens whose power exceeds the accommodative range of the cat<sup>10</sup>. This lens allows clear vision of horizontal contours but defocuses the image progressively more as the stimulus orientation approaches vertical. As such it simulates the clinical condition of astigmatism<sup>11</sup>.

Three kittens were reared from birth to 25 d old in the dark. They were then given visual exposure wearing goggles which forced one eye to view through the cylindrical lens while the other viewed normally, for 4-6 h per d for a total of 80-120 h. They were then returned to the dark until they were at least 3-months-old at which point single cell responses were examined in visual cortex. Our procedures for recording responses from single cortical cells are described elsewhere<sup>12,13</sup>. Kittens were initially anaesthetised with intravenous sodium thiopental and cortical units were recorded extracellularly with glass-coated platinum-iridium micro-electrodes. We used the sampling methods of Stryker and Sherk<sup>17</sup>, sampling units at intervals of approximately 100  $\mu$ m in order to minimise the bias of our recorded population. A blind procedure in which the experimenter knew neither the axis of the cylindrical lens, nor which eye wore the negative lens was used throughout the recording sessions. If the competition between the two eyes occurs at the orientation-selective cortical cell, the effect of the lens should be to give the normal eye a competitive advantage at cells preferring vertical stimuli and no competitive advantage at cells preferring horizontal stimuli. The 'cortical' mechanism proposed by Guillery<sup>6</sup>, thus predicts that the effect of the deprivation would be maximal at vertically-orientated cells and minimal at horizontally-orientated cells. If the competition occurs at a more peripheral level, where orientation selectivity among the cells is not present, the 'geniculate' mechanism predicts that the deprivation should reduce the effectiveness of the 'astigmatic' eye equally across cortical units of all orientations.

The distribution of ocular dominance for 292 units encountered in these kittens is shown in Fig. 2. As can be

**Fig. 1** The distribution of ocular dominance for units in the visual cortex of cats reared with one eye viewing through a cylindrical lens and the other eye viewing normally. The numbers on the abscissa from 1 to 7 represent a trend from the 'astigmatic' eye to the normal eye. Cells in group 1 are driven exclusively by the astigmatic eye; cells in group 4 are driven equally by both eyes; cells in group 7 exclusively by the normal eye. *a*, The distribution of ocular dominance for all cells in these cats. *b*, *c* and *d*, the distribution of ocular dominance as a function of the orientation of the unit. *b*, The vertical and *d*, the horizontal distributions represent cells which prefer orientations within 30° of vertical and horizontal. *c*, The 'diagonal' distribution represents cells preferring stimulus orientations within 15° of either diagonal. The hatched parts of the distribution represent cells in the hemisphere contralateral to the astigmatic eye.

seen, about twice as many units can be influenced through the normal eye as through the astigmatic eye. The distribution of ocular dominance is broken down according to the preferred orientation of the cortical units in the lower parts of Fig. 1. It is clear that the magnitude of the deprivation effect varies depending on the orientation preference of the cortical cell. It is marked for units preferring orientations within  $30^\circ$  of vertical, weaker for diagonally-orientated units and absent for units preferring horizontally-orientated ( $\pm 30^\circ$ ) stimuli. The results thus confirm the cortical hypothesis outlined earlier; they show that binocular competition occurs at the orientation-selective cortical cell and that this competition seems to be sufficient to account for all ocular dominance changes consequent to monocular image blur.

The total number of units encountered which prefer a particular orientation is shown for each eye separately in Fig. 2. The 'astigmatic' eye drives far fewer units which prefer vertically-orientated stimuli than units which prefer horizontal. The histograms in Fig. 2 show that the effect is similar in both hemispheres. One might imagine that this is a simple consequence of this eye having less exposure to focused stimuli with vertical orientations<sup>14-17</sup>. Such an explanation cannot, however, account for the striking bias in the distribution of preferred orientations which is evident in the normally-viewing eye. In this eye, 55% more cells prefer stimuli orientated within  $30^\circ$  of vertical than prefer stimuli within  $30^\circ$  of horizontal. This is at first glance surprising, since the normal eye has, after all, viewed all orientations with equal frequency and clarity. An examination of the histograms of Fig. 3 reveals that the distributions in the two eyes are complementary. The trough near vertical for the astigmatic eye is balanced by a corresponding bulge in the normal eye. Combining distributions for the two eyes, the total number of units encountered preferring vertical ( $\pm 30^\circ$ ) and horizontal ( $\pm 30^\circ$ ) is nearly identical. The overall distribution of orientation-selective

neurons in the visual cortex has remained unaltered but the normal eye seems to have made compensatory, orientation-selective inroads into the cortical territory normally occupied by the astigmatic eye.

The effects obtained here are not as marked as those which follow monocular eyelid suture during early development<sup>1,2</sup>. The latter case differs from ours in that the sutured eyelid almost completely obscures the stimulus while our negative lens merely blurs the image. The observed effects seem more marked in the hemisphere contralateral to the eye which wore the negative lens. This apparent asymmetry is probably attributable to the known preponderance of input from the contralateral eye to the visual cortex<sup>18</sup>. The normal contralateral bias would enhance the observed effects in one hemisphere and minimise them in the other.

A puzzle remains in the ocular dominance distribution for horizontally-orientated units where viewing conditions for the two eyes should be equal. While there is no tendency for either eye to control more neurones, the distribution lacks the usual complement of binocular neurones. The most likely explanation for this phenomenon is that the cylindrical lens was not perfectly centred on the kitten's eye. Even a small misalignment between the geometrical centre of the lens and the pupil would lead to prismatic displacement which could vary from day to day. This would mimic the situation in strabismus, a condition which is known to result in a loss of binocularly-driven neurones<sup>19</sup>.

Three main conclusions may be drawn from these results: first, asymmetric ocular refractive error during early development can cause severe changes in cortical binocular connectivity. Second, the mechanism of this disruption is a developmental competition between the two eyes which occurs at the visual cortex. And third, the cortical distribution of preferred orientations in a normally-viewing eye can be biased merely by depriving the other eye of focused input at certain orientations.

**Fig. 2** Distribution of preferred orientations for cortical units driven by *a*, the normal and *b*, the astigmatic eyes. On the right are polar plots in which each cell represents a single dot. The length of the dotted line along a given orientation is thus proportional to the number of units encountered which have this preferred orientation. On the left, the same data are presented in histogram form and are further subdivided by cortical hemisphere. The height of the bar at any orientation is proportional to the number of units preferring that orientation. The hatched part of the distribution is derived from the hemisphere contralateral to the astigmatic eye. The horizontal cells of the polar plots are divided equally between 9:00 and 3:00 on the associated histograms.

## Diffusion barrier for acetylcholine at the frog neuromuscular junction

INACTIVATION of acetylcholinesterase (AChE) causes the half-decay times of the endplate currents (e.p.cs) and miniature e.p.cs (m.e.p.cs) to increase from about 1.5-2.0 ms to 3.0-10.00 ms, times far too long to be accounted for by removal of the transmitter by free diffusion<sup>1-3</sup>. To explain this, Katz and Miledi<sup>1</sup> postulated

leptics inhibit  $^3\text{H}$ -haloperidol and  $^3\text{H}$ -spiroperidol binding in concentrations substantially lower than those which occur in the blood of patients at therapeutic doses. The radioreceptor assay described here is based on the principle that neuroleptics in the patient's serum compete for the binding of  $^3\text{H}$ -haloperidol or  $^3\text{H}$ -spiroperidol to dopamine receptors in membranes of the corpus striatum (S. H. S., unpublished).

In this assay, serum is used without any extraction or other purification procedure. The absence of interference by serum is apparent from experiments in which 15  $\mu\text{l}$  of serum in a total assay volume of 1 ml reduced  $^3\text{H}$ -haloperidol or  $^3\text{H}$ -spiroperidol binding by only 10–15%. Increasing volumes of serum reduced binding linearly with about 30% inhibition occurring with 150  $\mu\text{l}$  of serum. Small volumes of serum reduce both specific and non-specific  $^3\text{H}$ -ligand binding to similar extents suggesting that serum proteins bind  $^3\text{H}$ -ligand, making less available for interactions with brain membranes. The degree of inhibition of  $^3\text{H}$ -ligand binding by control sera from several laboratory personnel was uniform. Specific binding of  $^3\text{H}$ -haloperidol in the presence of 15  $\mu\text{l}$  of serum from 18 different subjects was  $91 \pm 1.6\%$  (total binding 2,325 c.p.m. blank with 0.1 mM dopamine 953 c.p.m.) of control values while specific  $^3\text{H}$ -spiroperidol binding was  $85 \pm 1.2\%$  (total binding 1,264 c.p.m. blank with 1 mM dopamine 191 c.p.m.) of control for 10 different subjects. This small degree of variability in inhibition of  $^3\text{H}$ -ligand binding by control sera falls within the error for repeated determinations of the same sample.

Neuroleptic present in a serum sample reduces  $^3\text{H}$ -ligand binding beyond the small reduction attributable to serum alone and the degree of inhibition of specific  $^3\text{H}$ -ligand binding is proportional to the amount of neuroleptic present. By constructing a standard curve of inhibition of specific  $^3\text{H}$ -ligand binding by known amounts of the drug, the amount present in a serum sample can be easily determined.

This method requires that the presence or absence of neuroleptic in a serum sample will not affect the degree of nonspecific (blank)  $^3\text{H}$ -ligand binding. In 46 serum samples from patients on neuroleptics, blank  $^3\text{H}$ -haloperidol binding was  $887 \pm 6$  c.p.m. while nonspecific binding in the presence of five control sera was  $894 \pm 17$  c.p.m. In six patients on haloperidol, nonspecific  $^3\text{H}$ -spiroperidol binding was  $199 \pm 4$  c.p.m. and  $198 \pm 6$  c.p.m. in the presence of six control serum samples. Thus specific binding in the presence of patient sera can be determined by subtracting nonspecific binding values obtained with control sera from total binding with patient sera. The percentage inhibition of specific  $^3\text{H}$ -ligand binding (in the presence of control serum) by the patient serum (containing drug) is then calculated and compared to a standard displacement curve for determining actual neuroleptic content.

Up to 99% of neuroleptics may be bound to blood components<sup>23,24</sup>. In this assay the neuroleptic bound to blood proteins dissociates during the incubation so that total neuroleptic levels are measured. In confirmation of this assumption in one experiment 15 nM haloperidol was preincubated for 10 min at 37 °C with control serum to allow binding to serum proteins to occur. The serum and haloperidol was then added to a standard binding assay which was at equilibrium and it progressively reduced  $^3\text{H}$ -haloperidol binding with increasing durations of incubation, with a maximal lowering by 5–10 min. The time course and extent of reduction of binding was the same for haloperidol pre-incubated with serum or simply dissolved in water. The maximum percentage lowering of binding was equivalent to that produced by 15 nM haloperidol added directly to the assay with no serum present.

For the neuroleptic radioreceptor assay fresh rat striatum was sonicated in 100 volumes (w/v) 50 mM Tris buffer, pH 7.7 at 25 °C with a Sonifier, setting 4 for 30 s. The homogenate was centrifuged twice at 50,000g for 10 min (Sorvall RC2-B) with rehomogenisation of the intermediate pellet in fresh buffer. The final pellet (which may be stored frozen) was resuspended in 125 volumes, for assays using  $^3\text{H}$ -haloperidol, or 285 volumes for  $^3\text{H}$ -spiroperidol, of freshly prepared 50 mM Tris buffer containing 0.1% ascorbic acid, 10  $\mu\text{M}$  pargyline, 120 mM NaCl, 5 mM KCl, 2 mM  $\text{CaCl}_2$  and 1 mM  $\text{MgCl}_2$  to give a final pH of 7.1 at 37 °C.  $^3\text{H}$ -Haloperidol (15 Ci mmol<sup>-1</sup>, New England Nuclear) or  $^3\text{H}$ -spiroperidol (26 Ci mmol<sup>-1</sup>, New England or Amersham) was diluted to 10 nM or 1 nM, respectively, in fresh 0.1% ascorbic acid. Glass 12  $\times$  75 mm incubation tubes received, in order, 15–150  $\mu\text{l}$  serum (on drug therapy or drug free), 100  $\mu\text{l}$   $^3\text{H}$ -ligand, 100  $\mu\text{l}$  drug for standard curve or dopamine for blanks ( $10^{-4}$  M for  $^3\text{H}$ -haloperidol and  $10^{-3}$  M for  $^3\text{H}$ -spiroperidol) or the drug solvent 0.1% ascorbic acid, and tissue suspension to 1 ml total volume. Final concentrations of  $^3\text{H}$ -haloperidol or  $^3\text{H}$ -spiroperidol were 1 nM and 0.1 nM respectively. The tubes were incubated at 37 °C for 10 min ( $^3\text{H}$ -haloperidol) or 15 min ( $^3\text{H}$ -spiroperidol) and rapidly filtered under vacuum through Whatman GF/B filters with three 5-ml rinses of ice-cold 50 mM Tris buffer, pH 7.7 at 25 °C.  $^3\text{H}$ -Ligand trapped on the filters was counted by liquid scintillation spectrometry after remaining overnight in scintillation vials containing NEN formula 947 fluor (New England Nuclear). A standard displacement curve for the drug under study was determined in the presence of equal volumes of control serum with final concentrations of the drug about one-third, three times and the same as its  $K_i$  value determined previously<sup>19,22</sup>. A log-probit plot was used to convert the displacement curve to a straight line so percentage inhibition of  $^3\text{H}$ -ligand binding can be easily converted to molar drug concentration (Fig. 1). In the presence of serum the ratio of total to nonspecific binding was about 2.4 for  $^3\text{H}$ -haloperidol and 6.6 for  $^3\text{H}$ -spiroperidol, so that the latter is the preferred ligand. Plasma can be used for assays if the KCl,  $\text{CaCl}_2$  and  $\text{MgCl}_2$  in the buffer are replaced by 5 mM sodium EDTA which prevents the plasma from clotting the brain homogenate. Neuroleptics can also be eluted from red blood cells by sonification and incubation in 0.1% ascorbic acid.

To examine recovery five neuroleptics were preincubated with serum for 10 min at 37 °C, to provide time for binding to serum proteins and subsequently assayed for

Fig. 1 Log-probit plots of neuroleptic inhibition of specific  $^3\text{H}$ -spiroperidol binding to rat striatal membranes.  $\blacktriangle$ , Thiordiazine;  $\square$ , chlorpromazine;  $\bullet$ , haloperidol;  $\triangle$ , fluphenazine.

neuroleptic levels. Haloperidol (0.1  $\mu$ M), fluphenazine (0.1  $\mu$ M), trifluoperazine (0.1  $\mu$ M), chlorpromazine (1  $\mu$ M), and thioridazine (1  $\mu$ M) were all fully recovered in the neuroleptic radioreceptor assay with respective values of  $0.11 \pm 0.02 \mu$ M ( $n=6$ ),  $0.12 \pm 0.01 \mu$ M ( $n=10$ ),  $0.16 \pm 0.2 \mu$ M ( $n=6$ ),  $1.0 \pm 0.1 \mu$ M ( $n=9$ ) and  $1.1 \pm 0.2 \mu$ M ( $n=6$ ). To examine the recovery of neuroleptics from the blood of patients treated *in vivo* we measured blood levels in four patients receiving oral doses of haloperidol both after extraction into organic solvent (heptane-5% isoamyl-alcohol, back extracted into 0.1% ascorbic acid) which should remove all drug bound to serum protein, and by adding serum directly to the binding assay as in the above method. Serum drug levels ranged between 10 and 250 nM and agreed within a mean of 10% whether assays were conducted with or without extraction.

To assess the validity of the radioreceptor assay, we compared its results with blood levels measured by other procedures. In one study, rats were given  $^3$ H-haloperidol 0.2 mg per kg body weight and blood levels of the drug were assessed by determining plasma radioactivity 10 min after drug administration or by radioreceptor assay following organic solvent extraction of the plasma. At this interval after  $^3$ H-haloperidol administration at least 75% of the radioactivity in plasma can be accounted for as unmetabolised haloperidol<sup>23</sup>. The blood level was  $130 \pm 30$  nM by measuring radioactivity and  $120 \pm 30$  nM by radioreceptor assay. In other studies, we measured blood haloperidol levels in patients whose levels were also determined by radioimmunoassay and found a good agreement between the two procedures (Table 1) (I.C., R. J. Wyatt and S.H.S., in preparation). Serum samples have been assayed fresh or after storage at or below  $-20^\circ\text{C}$ , but repeated freezing and thawing led to reduced measured neuroleptic levels. Using 150  $\mu$ l of serum the lower limit of sensitivity (15% inhibition of specific binding) is 1.8 ng ml<sup>-1</sup>, 2.2 ng ml<sup>-1</sup>, 2.5 ng ml<sup>-1</sup>, 8.6 ng ml<sup>-1</sup> and 30 ng ml<sup>-1</sup> for fluphenazine, trifluoperazine, haloperidol, chlorpromazine and thioridazine, respectively.

**Table 1** Comparison of radioreceptor assay (RRA) and radioimmunoassay (RIA) values for plasma levels of haloperidol

Patient samples	Dose level, Haldol (mg d <sup>-1</sup> )	Haloperidol (ng ml <sup>-1</sup> )	
		RRA	RIA
1	20	27	27
2	20	29	28
3	10	21	18
4	20	31	37
5	10	22	20
6	20	29	28

Aliquots of 30  $\mu$ l of patient plasma samples (previously frozen at  $-20^\circ\text{C}$ ) were assayed in the radioreceptor assay with  $^3$ H-haloperidol as ligand. A standard curve of  $^3$ H-haloperidol displacement was constructed from known amounts of haloperidol in the presence of control plasma. The radioimmunoassay<sup>28</sup> for haloperidol was performed by Drs Michael Shostak and James Perel, Columbia University.

In summary, this radioreceptor assay seems to offer a potential for routine application to large populations of patients. The procedure is sensitive. Since the milligram potencies of neuroleptics are closely correlated with their affinity for dopamine receptors labelled with  $^3$ H-haloperidol<sup>19,21</sup>, the sensitivity of the assay is greater for drugs which are used therapeutically at lower doses. At therapeutic doses of many neuroleptics, we have found the radioreceptor assay sensitive enough to determine drug levels in 15–30  $\mu$ l serum samples. But, where steady state blood levels are relatively low the sensitivity of the assay can be increased up to 10-fold by increasing the volume of serum (up to 150  $\mu$ l) added to the assay. The assay is selective for neuroleptics. Only dopamine receptor

antagonists compete with high affinity for  $^3$ H-haloperidol and  $^3$ H-spiroperidol binding. Levels of circulating catecholamines are much too low to pose any problem. In screens of large numbers of drugs from different chemical classes no drugs other than neuroleptics, except for ergots, compete significantly for  $^3$ H-haloperidol binding<sup>26</sup>. Ergots which do bind to dopamine receptors are not usually used clinically in the therapy of schizophrenics. Thus, this assay can be used in patients who are also receiving a variety of other drugs besides neuroleptics. For patients treated with two or more different neuroleptics, the absolute concentration of each drug cannot be separately determined. In these cases the total inhibition of  $^3$ H-haloperidol or  $^3$ H-spiroperidol binding can be converted to a 'chlorpromazine equivalent' which would produce the same degree of inhibition.

Another virtue of the assay is that it will detect metabolites which compete for dopamine receptor binding and thus may be therapeutically active. There is evidence that a substantial portion of the therapeutic activity of chlorpromazine might be contributed by its metabolite 7-hydroxychlorpromazine<sup>27</sup>. 7-Hydroxychlorpromazine has about 70% of the affinity of chlorpromazine itself for  $^3$ H-haloperidol binding sites<sup>28</sup> and hence would be detected in this assay.

The radioreceptor assay described here is simple to perform. Substantial quantities of corpus striatum tissue can be obtained from large animals such as calf or pig and stored frozen.  $^3$ H-Haloperidol and  $^3$ H-spiroperidol are commercially available. As many as 100 assays can be conducted in a morning.

We thank Drs A. Prange, R. Wyatt, J. Perel, P. Slavney and R. DiPaulo for clinical samples, T. Prosser for technical assistance and Susan M. Garonski and Carol Kenyon for manuscript preparation.

## Specific localisation of neurotensin to the N cell in human intestine by radioimmunoassay and immunocytochemistry

NEUROTENSIN, originally isolated from bovine hypothalamus<sup>1</sup>, was shown to be a peptide of 13 amino acids<sup>2</sup>. It has been synthesised<sup>3</sup> and its pharmacological actions shown to include effects on small intestine motility, blood vessel tone, enhancement of glycogenolysis, release of glucagon and inhibition of insulin release<sup>4-7</sup>. Immunoreactive neurotensin has been detected in mammalian hypothalamus and a few other areas of the brain<sup>8-10</sup> but much larger quantities occur in the intestine<sup>11</sup>. Neurotensin has been shown in discrete cells in the ileal mucosa of various birds and mammals including man<sup>12-15</sup>. The cell type has recently been fully characterised and its identity internationally accepted (see ref. 16). The distribution of the peptide in man is unknown. Using a combination of radioimmunoassay (RIA) and immunocytochemistry (IC) we have found large amounts of neurotensin-like reactivity in human ileum with less in the jejunum. The immunoreactive cells are restricted to the mucosa. Neurotensin thus joins the growing group of peptides which are common to brain and gut<sup>17</sup>. The effect of such peptides may differ according to their location. Neurotensin has been reported in rat blood<sup>11</sup> and may therefore act as a circulating hormone. In addition, its location in the brain suggests a possible role as a peptidergic neurotransmitter.

Fresh samples of human gastrointestinal tract were obtained during surgery for various disease states and were later found to be histologically normal. These included body and antrum of stomach, duodenum, jejunum, ileum, colon, pancreas and gall bladder. Part of the material was fixed in *p*-benzoquinone vapour<sup>18</sup> and part in purified glutaraldehyde<sup>19</sup> for ultrastructural studies. Pairs of serial 1- $\mu$ m resin-embedded sections were treated by an indirect immunocytochemical procedure with antisera to neurotensin and to one of the following peptides: somatostatin, glucagon, vasoactive intestinal peptide (VIP), gastrin, gastric inhibitory peptide (GIP) and cholecystokinin (CCK). The controls used included previous absorption of the antisera with glucagon, somatostatin, VIP, CCK, gastrin, GIP and neurotensin, at concentrations ranging from 2 to 25  $\mu$ g per ml of diluted antisera. Negative staining with anti-neurotensin was obtained only after inactivation with at least 10  $\mu$ g of synthetic neurotensin per ml of diluted antibody. Negative staining was also obtained by the use of normal rabbit serum instead of immune serum.

For radioimmunoassay a part of each surgical sample was extracted by boiling for 5 min in distilled water and two homogenisations. The tissue was then further extracted in 0.1 M formic acid. Both water and acid extracts were assayed at 10-fold serial dilutions. Antibodies for immunocytochemistry and radioimmunoassay were raised in rabbits to synthetic neurotensin coupled by carbodiimide to bovine serum albumin and by glutaraldehyde to bovine thyroglobulin. <sup>125</sup>I-Neurotensin was prepared by chloramine T oxidation and was stable at -20 °C for several months. The assay was sensitive to 10 pmol per tube and showed no cross reaction with any other gut hormone. Antibody interference by nonspecific effects was negligible, but was anyway unlikely because the assay sensitivity necessitated assay of extracts only in considerable dilution.

Many endocrine cells, stained solely with antibodies to neurotensin, were located in a restricted area of the gut, being especially numerous in the ileal mucosa. Their number diminished as the jejunum was reached and they were extremely sparse in the duodenum. Neurotensin immunoreactive cells were not detected in the mucosa of

stomach, pancreas or colon, or in any structure in the other layers of the gut wall. They were situated in the upper two-thirds of the villi (Fig. 1a) and were often seen to communicate with the intestinal lumen by means of microvilli (Fig. 1b). The cells were oval in shape and their secretory granules, located mainly in the basal parts of the cell (Fig. 1b), had an average size of 300 nm and a closely attached membrane (Fig. 1c). The neurotensin immunoreactive cells were not members of the argentaffin subgroup of APUD cells<sup>20</sup> since they were unstained with the Masson silver impregnation technique.

When serial 1- $\mu$ m sections were stained with antibodies reacting with enteroglucagon (EG) and VIP the positive cells were completely distinct from those stained by the neurotensin antibodies. The EG-positive cells contained

Fig. 1a, 1- $\mu$ m Araldite section stained for neurotensin. Arrow marks positive cell. A, gut lumen; B, lamina propria.  $\times 625$ . b, Serial 40-nm section showing same cell at EM. Arrow marks cell. A, gut lumen; B, lamina propria.  $\times 4,000$ . c, High magnification of cell to show detail of secretory granules.  $\times 14,000$ .

round granules with a mean diameter of approximately 260 nm and a closely attached membrane, which thus were considerably smaller than those of the N cell. The VIP-positive cells varied in shape and contained much smaller granules with a mean diameter of 120 nm and a closely attached membrane.

Thus neurotensin is confined to a single type of endocrine cell which has previously been overlooked in ultrastructural studies because of confusion with the EG(L) cells<sup>21</sup>. With the application of electron immunocytochemical methods it can now be seen that the cell contains granules of a type distinct from those of the other endocrine cells in the ileal mucosa.

Neurotensin immunoreactivity was detected by radioimmunoassay in high concentration in the ileal mucosa with lesser quantities in the jejunal mucosa (Table 1). Very much smaller quantities were found in whole thickness extracts of the wall of the stomach, duodenum and colon. It was undetectable in the pancreas and gall bladder.

**Table 1** Neurotensin immunoreactivity in various tissues

	Neurotensin (pmol per g wet weight)
Stomach (6)* full thickness	0.27 ± 0.03
Duodenum (7) full thickness	0.24 ± 0.10
Jejunum full thickness (2) mucosa (3)	0.80 (1.19, 0.42) 2.82 (4.62, 1.78, 2.07)
Ileum full thickness (2) mucosa (3)	12.0 (7.57, 16.4) 16.2 (23.1, 19.0, 6.5)
Colon (4)	0.50 ± 0.19
Gall bladder (3)	< 0.03
Pancreas (2)	< 0.03

Values are means ± s.e.m.

\*No. of determinations.

Neurotensin was originally extracted from the hypothalamus<sup>1</sup>, and its function there is no more clear than in the gastrointestinal tract. The morphological features of the neurotensin cells, which have microvilli and secretory granules located at the vascular pole, suggest they are sensitive to changes in the gut lumen which may thus provide the stimulus for the release of the peptide, presumably, because of the basal distribution of the neurotensin granule, directly into the circulation. This view is supported by the finding of neurotensin in rat plasma<sup>11</sup>. The restricted localisation of the peptide suggests that it may play a precise part in the sequence of post-digestive processes.

We thank Professor Enrico Solcia for useful discussions. This work was supported in part by the MRC, the Cancer Research Campaign, Volkswagenwerk Stiftung, Hannover and the Wellcome Trust.

## Hydration effects on the photocycle of bacteriorhodopsin in thin layers of purple membrane

THE purple membrane of *Halobacterium halobium* acts as a light-driven proton pump, producing a transmembrane proton gradient which is coupled to ATP synthesis<sup>1</sup>, and to phototaxis<sup>2</sup> in the intact bacteria. It contains a single type of protein, bacteriorhodopsin (BR) which spans a 45-Å membrane. The isolated purple membranes are flat oval sheets with an average diameter of 0.5 µm (refs 3, 4). Bacteriorhodopsin contains a retinal molecule (all-*trans* and 13-*cis*)<sup>5</sup> which is covalently bound via a protonated Schiff base to a lysine residue. It undergoes a photocycle described by the following scheme<sup>6–8</sup>:

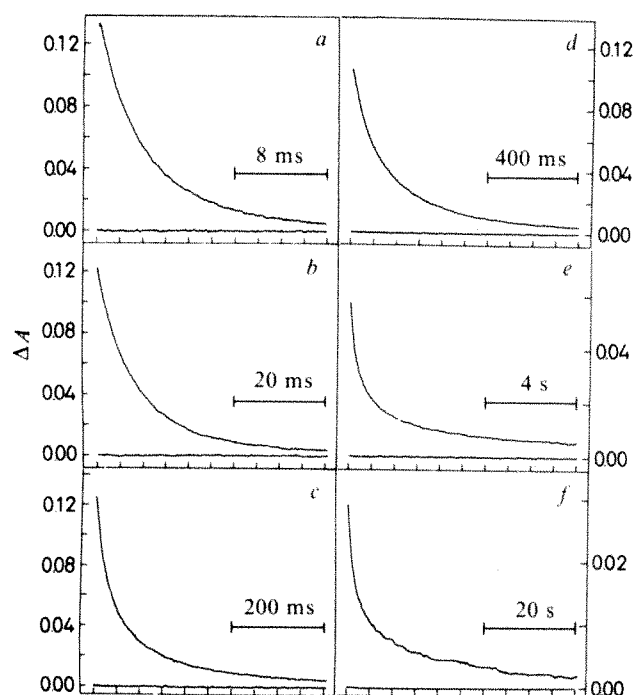

where proton ejection to the bulk solution occurs on the route '550' → '412' (refs 9, 10), whereas protonation of the bacteriorhodopsin takes place parallel to the '412' → BR<sup>570</sup><sub>all-trans</sub> process<sup>11</sup>. It has been reported that the reconstituted BR<sup>548</sup><sub>13-cis</sub> undergoes a cycle which involves the 'X' and the '610' intermediates<sup>12</sup>. It was demonstrated that proton transfer is a vectorial process where the proton is ejected from one side of the purple membrane and reprotonation takes place on the other side<sup>13</sup>. We present here results on the effects of the specific hydration of the purple membrane on the relaxation times of '412' and on the formation of the '660' and '610' intermediates. The results demonstrate that the full photocycle of bacteriorhodopsin can be observed in thin purple membrane layers even at the lowest hydration state and that the amount of absorbed water is rate limiting for the molecular process of the cycle.

Purple membranes were isolated from *H. halobium* (mutant NRL R<sub>1</sub>M<sub>1</sub>)<sup>5</sup>. Thin layers of purple membrane were prepared by drying concentrated suspension (3.5 × 10<sup>-4</sup> M) of the purple membrane in water (pH 7.2), on a glass slide. The drying was performed at atmospheric pressure, 45% relative humidity and 25 °C. The average thickness of the preparations was 1–3 µm as determined by scanning electron microscopy. Variable degrees of hydration of the purple membrane were obtained by equilibrating the samples with different relative air humidities produced by saturated salt solutions<sup>14</sup>. The glass slide with the preparations was inserted in a 1 × 1 cm cuvette and incubated in a desiccator at the required specific humidity for about 24 h. Before measurement the cuvette was immediately sealed within the desiccator with a Teflon plus Parafilm cover. The limit of dryness, obtained by drying the membrane at 10<sup>-3</sup> torr for approximately 4 h, was defined as the 0% relative humidity state.

Flash photolysis spectroscopy of thin-layer preparations of purple membrane show that bacteriorhodopsin undergoes a complete photocycle, involving the same intermediates characteristic of suspended purple membrane fragments in water. But the decay time of the '412' intermediate as well as the formation of '660' and '610' intermediates are determined by the specific hydration state of the membrane. Preparations equilibrated with 94% relative humidity show the same kinetics and

include the same transients as in purple membrane fragments suspended in water (Table 1). The relaxation times for '412' decay are slowed down by lowering the hydration state of the preparation (Fig. 1). The kinetics of '412' decay are analysed in terms of the sum of two or three exponentials (Fig. 2). The relaxation times and their relative amplitudes, at different hydration states, are given in Table 2. The initial values for the relaxation times and their corresponding amplitudes were obtained first graphically and then were optimised by a least square program (Harwell Subroutine Library, VCO5A). Essentially the same results were obtained when the initial values were calculated by a computer program (K. H. Mueller and T. Plessner, unpublished), within the frame of a non linear approximation<sup>15,16</sup>. The thermal decay kinetics of '412' could be enhanced by a factor of 15 when photobleached with 412-nm light at 0% relative humidity, in accordance with earlier experiments carried out with suspended purple membrane<sup>17</sup>.

The '660' and '610' intermediates are not formed at relative humidity lower than 90%. Moreover, the 660-nm intermediate cannot be detected at pH higher than 8 (in a solution of 4M

**Fig. 1** Oscilloscope traces obtained in flash photolytic measurements of thin purple membrane layers, kept in various hydration states. The traces represent the decay kinetics of '412' nm intermediate formed by a linearly polarised light pulse from a rhodamine 6G laser at 585 nm of 1  $\mu$ s duration. The samples were excited at right angles to the analysing light, where the plane of the thin purple membrane layers formed an angle of 45° both with the exciting and the analysis light axes. The amplified output of the photomultiplier passed through a variable RC filter to a digital scope, where the filter setting was such as to provide filter relaxation time equal to 0.05% of the oscilloscope's total time sweep width. The transient changes of '412' were recorded directly in absorbance units by the use of a lin-log converter. The flash experiments were performed with thin purple membrane equilibrated with the following relative humidities: a, 94%; b, 90%; c, 83%; d, 75%; e, 43%; f, 7%.

NaCl), or when suspending purple membrane in water-glycerol mixtures. In addition it has been shown that the formation of the '660' intermediate is temperature dependent<sup>18</sup>. Thus, the formation of this intermediate can serve as an internal probe of bacteriorhodopsin to environmental conditions, such as temperature, pH or relative humidity. The hydration effects were found to be fully reversible and each

**Table 1** Relaxation time constants ( $\tau_i$ ) of the '412', '660' and '610' intermediates

Intermediate	Purple membrane in water* ( $\tau$ , ms)	Thin purple membrane layers† ( $\tau$ , ms)
'412'	$1.7 \pm 0.6$ ( $0.21 \pm 0.13$ )	$1.8 \pm 0.2$ ( $0.3 \pm 0.07$ )
'660'	$5.0 \pm 0.8$ ( $0.79 \pm 0.13$ )	$5.4 \pm 0.9$ ( $0.69 \pm 0.07$ )
'610'	$5.4 \pm 0.4$	$5.6 \pm 0.6$
	$48 \pm 2.1$	$46.0 \pm 3.4$

The relaxation time constant is defined by  $A(t) = A_i e^{-t/\tau_i}$ , where the absorbance change is the sum of exponential terms. The relative amplitudes are given in brackets near the corresponding relaxation time constants. The experiments were done at room temperature ( $22 \pm 1^\circ\text{C}$ ).

\*Suspended purple membrane in water at pH 7.2.

†Thin purple membrane preparation equilibrated with 94% relative humidity.

sample was recycled through the various hydration states several times without noticeable irreversible changes.

The results show that the amount of adsorbed water on the purple membrane determines the relaxation times of the '412' decay. The changes in hydration cause a change of the relaxation times over four orders of magnitude (Table 2). It should be added that the rate of the photoactivated formation of the intermediates in the pathway leading to '412' is only changed to a minor degree as a function of the state of hydration. The observed three relaxation times suggest that bacteriorhodopsin undergoes either a three-step conformational change along with the '412'  $\rightarrow$  BR<sup>570</sup> transition or that '412' populates three conformations which decay to that of BR<sup>570</sup>. A similar interpretation was suggested earlier for the biphasic decay of '412' (refs 17, 19).

These effects could in principle be accounted for by a rate-limited diffusion of protons due to the amount and structure of the conducting water layers on the purple membrane or by a reversible conformation change induced by the hydration

**Fig. 2** Evaluation of data from Fig. 1d. The transient absorption  $A(t)$  is expressed as a sum of exponentials by  $A(t) = A_i e^{-t/\tau_i}$ , where  $A_i$  is the amplitude of the  $\tau_i$  relaxation time constant. Closed circles represent the original data points and crosses represent the calculated data points using  $\tau_1$ ,  $\tau_2$  and  $\tau_3$  as the relaxation time constants.

**Table 2** Relaxation time constants and amplitudes of the decay kinetics of '412' intermediate in thin layer preparations of purple membrane equilibrated in various relative air humidities

Relative air humidity (%)	$\tau_1$	$\tau_2$	$\tau_3$
90	3.5 $\pm$ 0.4 ms; (0.63 $\pm$ 0.05)*	13.1 $\pm$ 1.1 ms; (0.37 $\pm$ 0.03)*	252 $\pm$ 26 ms; (0.31 $\pm$ 0.05)*
83	10.2 $\pm$ 2.4 ms; (0.18 $\pm$ 0.03)	45 $\pm$ 3.3 ms; (0.52 $\pm$ 0.02)	503 $\pm$ 111 ms; (0.33 $\pm$ 0.08)
75	30.5 $\pm$ 7.0 ms; (0.11 $\pm$ 0.04)	124 $\pm$ 33 ms; (0.56 $\pm$ 0.08)	10.1 $\pm$ 3.0 s; (0.28 $\pm$ 0.06)
43	244 $\pm$ 100 ms; (0.30 $\pm$ 0.06)	1.25 $\pm$ 0.4 s; (0.42 $\pm$ 0.04)	28 $\pm$ 8 s; (0.36 $\pm$ 0.09)
10	0.9 $\pm$ 0.2 s; (0.28 $\pm$ 0.11)	4.0 $\pm$ 1.8 s; (0.35 $\pm$ 0.06)	154 $\pm$ 21 s; (0.40 $\pm$ 0.4)
0	2.3 $\pm$ 0.7 s; (0.28 $\pm$ 0.03)	15.7 $\pm$ 4.5 s; (0.32 $\pm$ 0.03)	

\*Amplitudes are shown in parentheses.

degree of the purple membrane. The possibility of a diffusional rate-limited proton transfer could be disregarded, however, as it would have imposed a continuous spectrum of relaxation times which is inconsistent with the observed data. The possibility of extreme pH changes due to changes in the amount of adsorbed water can be ruled out, since no spectral shifts of the absorption spectrum of the thin purple membrane layers were observed at different hydrations where a blue shift of the spectrum is expected at high pH and a red shift at low pH (ref. 20 and our unpublished data). A contribution of surface electrical potential changes of the purple membrane suspended in water was analysed by using high ion concentrations (1–4M NaCl) and increasing the pH up to 9. In this extreme case the decay of the '412' was only slowed down by a factor of 50.

Although changes in hydration were shown to control the conformation of proteins<sup>21</sup>, X-ray diffraction studies<sup>4</sup> of wet and dry specimen of the purple membrane have not shown any significant differences, possibly due to the fact that local changes might escape the sensitivity of the method applied with a 7-Å resolution. Indeed, hydration-induced conformational changes might be expected to occur in much smaller dimensions. Hydration can act either on the immediate environment of the retinal or through inducing a conformational change in the protein which is then transmitted to the retinal-protein interaction region. A possible induced conformational change may also involve an increased formation of internal hydrogen bonding on dehydration, competing for proton transfer, or a conformational induced pK shift of the terminal amino acids. It should be noted that the dehydration process may bring about a large change in the dielectric constant in the vicinity of the proton acceptor. Such a change can shift the pK by two to four units<sup>22</sup> and thus change the kinetics by orders of magnitude. Variation of the hydration state of the purple membrane may change the microviscosity of the lipids or even bring to phase separation. The influence of the lipid-protein interaction on the photocycle must be of a secondary importance, however, because no significant difference was found in the kinetics and in proton uptake of proteoliposomes prepared from lipid-depleted protein and from native purple membrane<sup>23</sup>. The conformation change is further supported by the observation of a decoupling of the *cis-trans* isomerisation process as a function of hydration<sup>24</sup>, as well as by the photochemical bleaching of the '412' intermediate even at the lowest humidity state. In addition, dehydration of vertebrate rhodopsin was found to stop the meta I  $\rightarrow$  meta II transition<sup>25</sup>. Thus in both bacteriorhodopsin and in rhodopsin those conformational changes which involve both protonation-deprotonation reactions and large enthalpy change are those which are most effected by dehydration.

These results stress the importance of the state of hydration in bacteriorhodopsin, presumably as a conformation-controlling event, which might be of general significance for energy transducing membranes especially in the case where deprotonation and protonation processes, coupled to conformation changes are an inherent part of the energy transformation process. The results also indicate that the photochemical reaction is independent from the state of the bulk

solution and is only influenced by the microenvironment of the reaction system which operates in a state of quasi isolation.

We thank Mrs Renate Müller for technical assistance and Dr D. Kuschmütz for helpful discussions.

## Detection of carcinogen-DNA adducts by radioimmunoassay

COVALENT binding of carcinogen to nucleic acids is believed to be an essential component of the carcinogenic process<sup>1</sup>, so it is desirable to have highly sensitive and specific methods for detecting such adducts in cells and tissues exposed to known and suspected carcinogens. We describe here a radioimmunoassay (RIA) capable of detecting nanogram amounts of DNA adducts resulting from the covalent binding of the carcinogen *N*-2-acetylaminofluorene (AAF) and its activated derivative *N*-acetoxy-AAF (*N*-Ac-AAF) are potent carcinogens<sup>2</sup> and mutagens<sup>3,4</sup>, and transform cells in culture<sup>5,6</sup>. DNA obtained from rat liver following *in vivo* exposure to AAF, and DNA exposed *in vitro* to *N*-Ac-AAF contain as the major (80%) adduct *N*-(deoxyguanosin-8-yl)-acetylaminofluorene (dG-8-AAF)<sup>7–9</sup> and a minor (20%) adduct 3-(deoxyguanosin-5-yl)-acetylaminofluorene (dG-*N*-2-AAF)<sup>10</sup>. These two types of modification produce markedly different conformational effects on the DNA helix<sup>2,11,12</sup>. The major adduct, recognised by

single strand-specific nucleases *in vitro*<sup>13,14</sup> and DNA repair enzymes *in vivo*<sup>9,15</sup> was used as the immunogen in this study.

Guanosine (Sigma) and *N*-Ac-AAF (Midwest Research Institute), each at 4.6 mM in 30% ethanol, were incubated for 24 h at 37 °C. The resultant *N*-(guanosin-8-yl)-acetylaminofluorene (G-8-AAF) was separated from the reaction mixture using a 20–100% methanol gradient on Sephadex LH-20 (Pharmacia) and rechromatographed until it gave a characteristic absorption spectrum<sup>8</sup>. The purified product (9 mg) was coupled to bovine serum albumin (BSA, 35 mg, Sigma) by NaIO<sub>4</sub> oxidation followed by NaBH<sub>4</sub> reduction<sup>16</sup>, yielding 3.5 mg of covalently bound G-8-AAF ( $\Sigma_{305} = 1.5 \times 10^4$ ). Three rabbits were immunised with G-8-AAF-BSA initially in complete and then in incomplete Freund's adjuvant at weeks 0, 1, 3, 12, 15, 17 and 23. Injections of 0.3 mg hapten were given intramuscularly in the hind legs. Blood was taken from the ear veins before immunisation, at 1 and 2 months, and weekly between 2 and 5 months. All three rabbits produced high levels of antibody by 4 months when assayed by RIA.

For RIA, the tracer, <sup>3</sup>H-dG-8-AAF (6 Ci mmol<sup>-1</sup>) was synthesised from *N*-Ac-AAF and deoxyguanosine (8,5'-<sup>3</sup>H, 29 Ci mmol<sup>-1</sup>, NEN), as described above for G-8-AAF. During chromatography on Sephadex LH-20, an initial small radioactive peak, (the presumed dG-N2-AAF<sup>9,10</sup>), was discarded and the major radioactive peak (dG-8-AAF) was collected and rechromatographed twice on Sephadex LH-20. A standard curve for RIA was constructed by competing the <sup>3</sup>H-dG-8-AAF with unlabelled G-8-AAF or dG-8-AAF, both of which competed equally well. High-titre serum was diluted at least 1:300 (Fig. 1). For equilibrium conditions, <sup>3</sup>H-dG-8-AAF, antiserum and inhibitor were incubated at 37 °C for 2 h, followed by goat anti-rabbit-IgG (GAR-IgG, Miles) at 22 °C or 4 °C for a minimum of 1 h. After centrifugation the supernatant was discarded and the pellets were dissolved in 0.1 M NaOH and counted. In these conditions 5–6 ng of unlabelled standard gave a 50% inhibition of antibody-bound label. The standard curves were analysed by computer program, RIAPROG<sup>17</sup>, which confirmed the linearity of the RIA by Scatchard plot. An alternate method

**Fig. 1** Radioimmunoassay standard curve at equilibrium conditions (see text) using diluted antiserum (1:1000 in 0.01 M Tris pH 7.6) (dashed line) or purified antibody diluted 1:5 in 0.01 M Tris pH 7.6 (solid line). The reaction mixture containing 0.1 ml antibody, 0.1 ml <sup>3</sup>H-dG-8-AAF (6 Ci mmol<sup>-1</sup>, 40,000 c.p.m.) and various concentrations, in 0.1 ml of G-8-AAF (○), *N*-Ac-AAF (●) or dG (△) was incubated for 2 h at 37 °C. Goat anti-rabbit-IgG (GAR-IgG, Miles) was diluted 1:2 in water and 0.1 ml added per tube. After incubation for an additional hour at 22 °C or 4 °C, the precipitate was collected by centrifugation, dissolved in 0.2 ml 0.1 M NaOH, and counted in Aquasol-2 (NEN), in a Beckman LS-250 scintillation counter. Two to four replicates were assayed per point and values agreed within  $\pm 5\%$ . A blank of about 800 c.p.m., obtained with non-immune serum, was subtracted from each assay. Concentrations of diluted antiserum or purified antibody were chosen such that about 10,000 c.p.m. were bound in the absence of an inhibitor, and this value was taken as 100%.

**Fig. 2** RIA of *N*-Ac-AAF-modified and non-modified *M. luteus* DNA in differing physical circumstances. *M. luteus* DNA (32 mg, Miles) was heated to 100 °C for 10 min, cooled rapidly in ice and incubated with 36 mg of *N*-Ac-AAF in 17% ethanol in SSC (total volume 42 ml) for 18 h at 37 °C. The reaction mixture was extracted seven times with either, reprecipitated with 70% ethanol to a stable  $A_{260}/A_{270}$ , and collected by centrifugation (150,000g, 4 °C, 48 h). Conditions for the RIA, using G-8-AAF as standard, were as in the legend to Fig. 1. Modified (○) or unmodified (●) DNA were assayed without further treatment (---), after heating to 100 °C for 10 min (—) or after enzymatic digestion (—). The enzymatic digestion was performed as follows: samples containing 500  $\mu$ g DNA were incubated per 0.5 ml of reaction mixture, with 20 units DNase I (Worthington), 5  $\mu$ mol MgSO<sub>4</sub> and 30  $\mu$ mol sodium acetate pH 5.5, at 37 °C for 4 h. The pH was then adjusted to 8.5 with (NH<sub>4</sub>)<sub>2</sub>CO<sub>3</sub> and 20 units venom phosphodiesterase (VP, Worthington) and 1.5 units alkaline phosphatase (AP, BAPC, Worthington) were added to 1 ml of reaction mixture followed by incubation for 18 h at 37 °C. After boiling for 10 min to denature the enzyme protein, samples were cooled on ice, centrifuged (5,000g, 4 °C) to remove the protein precipitate and the supernatant diluted in 0.01 M Tris pH 7.6 for RIA. The actual ng of dG-8-AAF per ng DNA were determined by comparing the values for % inhibition with a simultaneously-run standard curve similar to Fig. 1. The amount of DNA was calculated from  $A_{260}$ , by diphenylamine<sup>20</sup> reaction and by a fluorescence assay<sup>21</sup>, all of which agreed within 10%.

for increasing the sensitivity of the assay is the use of non-equilibrium conditions, in which the labelled hapten is added for much shorter periods of time, thus enhancing the competition of the test compound. Antibody and unlabelled standard or inhibitor were incubated for 2 h at 37 °C and cooled to 4 °C for 10 min. Tracer was then added, followed 5 min later by GAR-IgG and samples kept at 4 °C for 45 min before centrifugation. In these conditions 1 ng of either G-8-AAF or dG-8-AAF gave a 50% inhibition.

Using the RIA at equilibrium conditions the specificity of the antiserum was tested against deoxyribonucleosides, AAF and related compounds. As shown in Fig. 1, whereas 2–5 ng of G-8-AAF produced a 50% inhibition, up to 100  $\mu$ g of dG was inactive. *N*-Ac-AAF as well as AAF and *N*-OH-AAF (data not shown) produced a slight inhibition only at a very high concentration, and up to 100  $\mu$ g of dT, dA, and dC were totally ineffective (data not shown).

Antibody specific to G-8-AAF was purified from the above antiserum by affinity chromatography. Agarose- adipic hydrazide (Miles) was coupled covalently to G-8-AAF by NaIO<sub>4</sub> oxidation<sup>18</sup>, yielding 3  $\mu$ mol G-8-AAF per ml packed Agarose. Antiserum was passed through the column and 90% of the antibody activity remained bound. Elution was accomplished either by alternate washes with 0.2 M glycine pH 2.5, and 0.01 M Tris pH 7.6, or with a 5–7 M urea gradient, increased stepwise. The purified antibody showed greater sensitivity for G-8-AAF (2.5 ng gave 50% inhibition at equilibrium) than the unfractionated antiserum, and the same specificity as the diluted antiserum with respect to nucleosides and AAF derivatives (Fig. 1). The amount of purified antibody recovered was

equivalent to 20% of the binding capacity of the starting antiserum.

To define further the specificity and sensitivity of the RIA, the G-C rich DNA from *Micrococcus luteus* was extensively modified by reaction with *N*-Ac-AAF *in vitro* as described in Fig. 2. The amount of dG-8-AAF, when determined by  $A_{305}$ , indicated that 28% of the nucleotides contained covalently-bound AAF residues. A similar high degree of modification, representing 70–80% of G substitution, has been previously reported for *M. luteus* DNA reacted with *N*-Ac-AAF<sup>19</sup>. But, when assayed initially by RIA this DNA gave values indicating a 1.6% modification (Fig. 2). If the DNA was denatured by heating before RIA, values indicated a 5.5% modification. Finally, when the DNA was hydrolysed enzymatically and the digest assayed by RIA, a 27% modification, corresponding closely to that predicted by the spectral method, was observed (Fig. 2). Thus the antibody recognises only a fraction of the dG-8-AAF residues in intact DNA but quantitative detection is obtained when the DNA is hydrolysed. The 1.6% modification observed before heat-denaturation or hydrolysis might be due to partially denatured regions or AAF binding near the ends of DNA strands. These results are consistent with evidence that most of the covalently-bound AAF residues lie inside the polynucleotide structure stacked with adjacent bases<sup>11</sup> and, therefore, presumably shielded from optimum interaction with the antibody. It is of interest that antibodies to other naturally occurring modified nucleosides recognise residues in denatured, rather than native, DNA<sup>20–23</sup>.

This RIA has also been useful in detecting the extremely low levels of carcinogen modification of DNA that occur in *in vitro* conditions. As shown in Table 1, when cultured primary mouse epidermal cells were exposed to  $10^{-4}$ – $10^{-6}$  M *N*-Ac-AAF, a concentration-dependent increase in binding of AAF to cellular DNA was detected by the RIA. The results shown were reproduced in four separate experiments, although the extent of binding varied by a factor of 2 with different batches of primary cultures. Factors contributing to this type of variability with primary epidermal cell cultures have been previously discussed<sup>24</sup>. At an exposure concentration of  $10^{-6}$  M the amount of dG-8-AAF detected in three experiments (data not shown) ranged from 3.5 to 10  $\mu$ mol dG-8-AAF per mol DNA-P. These values are similar to those reported for binding measured by the specific

activity of DNA following the exposure of mouse 3T3 cell cultures to  $10^{-6}$  M  $^{14}$ C-*N*-Ac-AAF for 1 h (ref. 25).

These results indicate that the covalent binding of a chemical carcinogen, AAF, with nucleic acids can be readily detected by RIA with a specific antiserum to the carcinogen-nucleoside adduct. The complete cross-reactivity between G-8-AAF and dG-8-AAF was to be expected since the bovine serum albumin carrier was linked through the 2' and 3' OH groups of the ribose. It is remarkable that our antiserum specifically recognises the AAF-nucleoside complex, but not free AAF, or nucleoside. This specificity is of particular importance for a carcinogen like AAF where two guanosine adducts have been described. Our antigen contained only the C-8 adduct, so it is likely that our antibody detects mainly the corresponding adduct in DNA. Studies are in progress to determine whether or not there is significant cross-reactivity with dG-N<sup>2</sup>-AAF. It is possible that each type of adduct will have immunological specificity and can be independently assayed with high sensitivity during the process of AAF carcinogenesis. The usefulness of this immunological approach may be extended to other types of studies and other classes of carcinogens. Experiments to measure removal of carcinogen by DNA repair processes are in progress, and assays for the possible covalent binding of suspected environmental carcinogens to human tissues should also be feasible.

We thank Drs Bernard Erlanger, John Langone, Steven Leppia, Mark Zweig and Peter Munson for useful discussions, and Ms Brigitte Former and Mr Marc Dubin for technical assistance. This work was supported in part by NCI DHEW grant CA21111-01.

**Table 1** Detection of dG-8-AAF by RIA in DNA from cells exposed to *N*-Ac-AAF

Concentration of <i>N</i> -Ac-AAF	Content of dG-8-AAF			
	Exp 1		Exp 2	
	ng per 100 $\mu$ g DNA	$\mu$ mol per mol DNA-P	ng per 100 $\mu$ g DNA	$\mu$ mol per mol DNA-P
$1.0 \times 10^{-6}$ M	0.57	3.5	NT	—
$1.5 \times 10^{-6}$ M	$2.56 \pm 0.6$	$15.6 \pm 3.5$	1.6	9.7
$5.0 \times 10^{-6}$ M	5.44	33.1	$2.44 \pm 0.2$	$14.8 \pm 0.8$
$5.0 \times 10^{-4}$ M	13.40	81.5	6.28	38.2

Primary BALB/c epidermal cells were prepared from newborn mice<sup>21,26</sup>, and  $2.4 \times 10^6$  cells were plated in roller bottles (Bellco, 825 cm<sup>2</sup>). On day 3, the indicated concentration of *N*-Ac-AAF dissolved in dimethylsulphoxide (DMSO) or DMSO alone, was added to the medium for 1 h at 37 °C, after which the cells were collected and DNA isolated and purified as previously described<sup>15</sup>. The DNA was then hydrolysed enzymatically as described in Fig. 2 and duplicate aliquots containing approximately 25  $\mu$ g of DNA and 50  $\mu$ g of DNA (0.025 and 0.05 ml respectively) were assayed by RIA using non-equilibrium conditions (see text). Identical results were obtained at both DNA concentrations. A standard curve was constructed from equivalent amounts of untreated and hydrolysed BALB/c epidermal DNA to which were added known nanogram quantities of dG-8-AAF. Control DNA from cultures not exposed to *N*-Ac-AAF did not inhibit the RIA. Values listed in the table refer to DNA from one bottle of treated cells except in cases (\*) where the mean  $\pm$  the range for three bottles has been given. NT, not tested.

## Specific poly-A-binding protein of 76,000 molecular weight in polyribosomes is not present on poly A of free cytoplasmic mRNP

CYTOPLASM of animal cells contains mRNA associated with ribosomes (in polysomes) and mRNA free of ribosome attachment. Both classes of mRNA occur as ribonucleo-protein (mRNP) complexes<sup>1-3</sup>. The role of the untranslated pool of free mRNA (referred to as informosomes<sup>3</sup>) is uncertain. They represent the form in which mRNA exists in transit from the nucleus to the cytoplasm awaiting association with ribosomes<sup>3</sup>, and in addition the pool of free cytoplasmic mRNA contains inactive (or inactivated) and storage forms of mRNA<sup>4</sup>. It has been established that most of the polysomal mRNP complexes contain predominantly two proteins with approximate molecular weights (MW) of 49,000–52,000 and 73,000–78,000 respectively<sup>5-9</sup>. It is generally accepted that the larger of these proteins is attached to the 3' poly A tail of

**Fig. 1** Autoradiograph of a polyacrylamide gel showing patterns of proteins present in oligo dT-cellulose-purified polyribosomal and informosomal mRNP from Ehrlich ascites tumour cells. Ehrlich ascites tumour cells were labelled with <sup>35</sup>S-methionine in the presence of low concentrations of actinomycin D and ethidium bromide (0.04  $\mu\text{g ml}^{-1}$  and 1  $\mu\text{g ml}^{-1}$ , respectively) as described previously<sup>13</sup>. Polyribosomes were pelleted through a 2 M sucrose layer containing 0.5 M KCl and free cytoplasmic mRNP was pelleted from the post-ribosomal supernatant in the presence of 0.5 M KCl by a 24-h centrifugation at 200,000g. The polyribosomes and informosomal mRNP pellet were suspended in a 200 mM NaCl, 50 mM Tris-HCl, pH 7.8, 10 mM EDTA solution containing 0.2% Nonidet-P40 and applied onto an oligo dT-cellulose column. Elution of the adsorbed mRNP particles was as described by Lindberg and Sundquist<sup>7</sup>. The formamide eluted mRNP particles were analysed by electrophoresis in sodium dodecylsulphate (SDS) on 7–18% polyacrylamide gradient gels<sup>10</sup>. Channel 1, <sup>35</sup>S-labelled proteins present in polyribosomal mRNP. Channel 2, <sup>35</sup>S-labelled proteins present in informosomal mRNP. The indicated MWs were extrapolated from the positions of marker proteins (not shown): phosphorylase b (MW 92,000), bovine serum albumin (68,000), ovalbumin (45,000),  $\alpha$  A<sub>2</sub>-crystallin (20,000) and cytochrome c (12,000).

**Fig. 2** Zonal centrifugation profiles of EDTA-dissociated polyribosomes (a) and of informosomes (b) from rabbit reticulocytes. Polyribosomes were isolated from rabbit reticulocyte lysates and, after washing with 0.5 M KCl, were suspended in 10 mM Tris-HCl, pH 7.4, containing 30 mM EDTA. The post-polysomal supernatant of the lysate was centrifuged for 24 h at 78,000g. The pellet, containing the informosomal mRNP was suspended in 10 mM Tris-HCl, pH 7.4. About 2,000  $A_{260}$  units of each sample (EDTA-treated polyribosomes and informosomes) were applied onto 0–42% (w/w) zonal sucrose gradients in 10 mM Tris-HCl, pH 7.4. The mixing volume was 750 ml and overlayer and sample volumes were 550 and 50 ml, respectively. 180 ml of the gradient was used in the overlayer. Centrifugation was carried out at 35,000 r.p.m. for 21 h at 4 °C using the IEC B29 rotor. The gradient was analysed at 260 nm (2-mm flow cell) with a continuous monitoring system and the part of the gradient containing the mRNP particles (hatched area) was pooled.

mRNA<sup>10-12</sup>. We present evidence here that the poly A segments of non-polysomal mRNA of Ehrlich ascites tumour cells and of rabbit reticulocytes—in contrast to the polysomal poly A segments<sup>10-13</sup>—do not contain the 76,000 MW protein.

Ehrlich ascites tumour cells were labelled with <sup>35</sup>S-methionine in the presence of low concentrations of actinomycin D and ethidium bromide. In these conditions the proteins present in mRNP complexes were labelled whereas little radioactivity was incorporated in the proteins of high salt washed polyribosomes<sup>13,14</sup>. The oligo dT-cellulose procedure of Lindberg and Sundquist<sup>7</sup> was used to purify the poly A-containing mRNP present in polyribosomes and informosomes. The 50% formamide eluate was analysed by sodium dodecylsulphate-polyacrylamide gel electrophoresis<sup>15</sup> followed by scintillation autoradiography. The result is shown in Fig. 1. The high degree of similarity between the protein patterns of both classes of mRNP particles is

**Fig. 3** Electrophoretic analysis of the products of *in vitro* translation of purified informosomal 15S mRNP and 9S polysomal and informosomal mRNA from rabbit reticulocytes. A cell-free system from Ehrlich ascites tumour cells growing in suspension culture<sup>13</sup> was prepared as described by Hunt<sup>25</sup> and treated with micrococcal nuclease as described by Pelham and Jackson<sup>26</sup>. Purified polysomal and informosomal 9S mRNA and 15S informosomal mRNP were added to the incubation mixture (25  $\mu$ l) containing 15  $\mu$ l Ehrlich ascites extract and 2  $\mu$ l nuclease treated 0.5 M KCl wash of rabbit reticulocyte polyribosomes (initiation factors). Haemin (25  $\mu$ M) and other ingredients in the concentration described previously<sup>27</sup> were added. Incubation was for 1 h at 30 °C. Part of the incubation mixture was boiled in SDS-sample buffer and loaded onto 13% (w/v) slab gels in a buffersystem described by Weber and Osborn<sup>28</sup>. Slab gels were prepared for scintillation autoradiography as described before<sup>29</sup>. Channel 1, products synthesised by polyribosomal 9S mRNA. Channel 2, product synthesised by mRNA isolated from purified informosomal mRNP. Channel 3, product synthesised by purified informosomal mRNP. Channel 4, labelled  $\alpha$ - and  $\beta$ -globin markers.

apparent. But, the predominant 76,000 component present in polysomal mRNPs was absent in newly-synthesised informosomal mRNPs. Exhaustive degradation of informosomes from these cells with ribonucleases released poly A-protein complexes containing stretches of poly A of about 90–110 adenyl residues and a predominant 84,000 MW protein<sup>16</sup>. (In a Laemmli gel<sup>15</sup> as has been used in this work this protein was visible as a double band around 89,000 MW (Fig. 1, slot 2).) The fact that the poly A segments of these newly-synthesised mRNPs were considerably longer than the polysomal poly A segments in these cells (about 70 adenyl residues<sup>13</sup>) is an indication that we were dealing with young 'transit' mRNPs in contrast to old inactive forms of mRNPs with smaller poly A segments<sup>17–20</sup>.

To establish whether the old inactive forms of informosomal mRNPs also lack the specific poly A-binding protein of 76,000 MW, polysomal and informosomal mRNP were isolated from rabbit reticulocytes. These cells synthesise predominantly the  $\alpha$  and  $\beta$  chains of haemoglobin which are encoded by a 9S mRNA. Another characteristic of these cells is that the free cytoplasmic 9S mRNA primarily codes for the  $\alpha$  globin chain<sup>21,22</sup>. It represents mainly old mRNA characterised by a relatively small poly A segment<sup>17</sup>.

Reticulocyte polyribosomes and informosomes were isolated as described in Fig. 2 legend. The polysomal mRNP sedimented as a 15S particle (Fig. 2a), while the free cytoplasmic mRNP had S-values ranging from 15 to 20S (Fig. 2b). Both classes of particles contained 9S mRNA that

could be adsorbed on oligo dT-cellulose and eluted with a low salt buffer as described by Aviv and Leder<sup>23</sup>. The presence of a poly A tail in the informosomal mRNP was further established by hybridisation with <sup>3</sup>H-poly U (ref. 24) (data not shown).

Translation of the polysomal and informosomal mRNP and their respective mRNA was performed in a cell-free system prepared from Ehrlich ascites tumour cells<sup>25</sup> treated with micrococcal nuclease as described by Pelham *et al.*<sup>26</sup>. Figure 3 shows that polysomal 9S mRNA coded for  $\alpha$  and  $\beta$  globin, a result that is in agreement with various earlier reports. The major product synthesised by the informosomal mRNP and its 9S mRNA was  $\alpha$  globin (slot 3 and 2, respectively). The fact that free cytoplasmic mRNA (mRNP) from rabbit reticulocytes coded primarily for the  $\alpha$  globin chain has been described earlier<sup>21,22</sup> and corroborated the assumption that our 15–20S mRNP preparation was not significantly contaminated by polysome derived mRNA (or mRNP). The observation of Civelli *et al.*<sup>30</sup> that duck erythroblast informosomes are not translated (in a wheat germ cell-free system), suggests that unknown components in the cell-free system are required for translation of these particles.

The protein composition of the 15S polysomal and 15–20S informosomal mRNP particles is shown in Fig. 4. Molecular weights were calculated using a series of marker proteins with known MW. In the polysomal mRNP the 76,000 MW protein and two proteins around 50,000 MW were prominent. A series of about six bands between 24,000 and 34,000 MW (four of them more prominent) was also a characteristic feature of the mRNP composition. The latter series of six bands was also present in informosomal mRNP. It is clear, however, that the 76,000 MW protein is not present although the informosomal mRNA contains a 3' poly A tail (see above). The protein bands around 58,000 MW (consisting of at least three proteins as could be seen in more clearly separated electrophoresis patterns) visible in slot D were removed when 15–20S informosomes were washed with 0.5 M KCl. The particles then were converted into predominantly 15S mRNP particles containing  $\alpha$  9S mRNA and the series of six bands which were probably proteins more firmly attached to the mRNA (slot i).

We conclude that poly A-containing informosomal mRNA in Ehrlich ascites tumour cells and in rabbit reticulocytes do not contain the 76,000 MW protein which in these and most other cells is associated with the poly A of polysomal bound mRNA. In view of the fact that the size of the polyadenylate segment of mRNA shortens when the message ages<sup>17–20</sup> we suggest that both poly A and the protein associated with it are degraded during ageing of mRNA. Newly-synthesised mRNA not associated with ribosomes (for example in Ehrlich ascites tumour cells) has a protein of MW 84,000–89,000 attached to its relatively long poly A segment<sup>16</sup>, whereas a 76,000 MW is attached to the poly A of mRNA in the translational phase. Later on, the mRNA (for example the informosomal  $\alpha$ -globin 9S mRNA) is released into the pool of untranslated mRNA. In this phase only low-MW proteins, if any, are attached to the shortened poly A segments. It is tempting to speculate that the loss of the 76,000 MW protein and shortening of the poly A tail are cooperative processes which are closely related to the functioning and/or stability of the mRNA.

During the preparation of this manuscript Scherrer's group<sup>31</sup> published the protein composition of informosomal mRNP from duck erythroblasts. In agreement with our observations they also found no 76,000 MW protein associated with poly A-containing informosomal mRNP.

We thank Drs F. A. Asselbergs and A. J. M. Berns for help and advice and A. P. M. Janssen for technical assistance. This work was supported in part by the Netherlands

**Fig. 4** Analysis of proteins present in purified polysomal and informosomal mRNP particles from rabbit reticulocytes. mRNP particles were dissolved in SDS-sample buffer, boiled and loaded on to a 7–18% polyacrylamide gradient gel containing SDS<sup>15</sup>. Channels *a*, *e*, *h*, marker proteins:  $\beta$ -galactosidase (MW 130,000), phosphorylase b (92,000), bovine serum albumin (68,000), ovalbumin (45,000),  $\alpha$ A<sub>2</sub>-crystallin (20,000), cytochrome *c* (12,000). *b*, Polysomal 15S mRNP. *c*, Informosomal mRNP after a 0.5 M KCl wash (see also *i*). *d*, Informosomal mRNP before the 0.5 M KCl wash. *f*, EDTA-treated 40S ribosomal subunits. *g*, EDTA-treated 60S ribosomal subunits. *i*, Informosomal mRNP after a 0.5 M KCl wash (double band at 20,000 is carrier  $\alpha$ -crystallin). *k*, 0.5 M KCl wash of informosomal mRNP (double band at 20,000 carrier is  $\alpha$ -crystallin).

## Corrigendum

In 'Voltage signal of photoreceptors at visual threshold' by G. L. Fain, A. M. Granda and J. H. Maxwell (*Nature* **265**, 181; 1977), the ordinate label of Fig. 1 should read:  $\log \Delta I_T$  ( $\mu\text{J cm}^{-2} \text{ flash}^{-1}$ ). Likewise, the abscissa label of Fig. 1 should read:  $\log \Delta I_T$  ( $\mu\text{J cm}^{-2} \text{ s}^{-1}$ ). This is simply a labelling error and has no effect on any numbers in the text. The authors are grateful to Dr G. S. Wasserman of Purdue University for pointing out this error.

## Errata

In the article 'Corrected age of the Pliocene/Pleistocene boundary' by B. U. Haq, W. A. Berggren & J. A. Van Couvering, *Nature* **269**, p. 483, the legend to Fig. 5 should read . . . Pliocene/Pleistocene calcareous plankton biochronology in deep-sea cores and estimated chronostratigraphic position of Calabrian sequences. The extinction of *Discoaster brouweri* occurs at about 1.8 Myr (\*) in one of the cores studied (V12–18). The upper limit of this species, as shown here, may thus be somewhat younger than the actual extinction datum, due to reworking at the depositional interface. ○, Atlantic only.

In the letter 'Corollary discharge to cockroach giant interneurons' by F. Delcomyn, *Nature* **269**, p. 160, line 17 in paragraph 4 should read . . . When a strong stream of air is suddenly turned on a quiet . . .

In the letter 'Direct measurements of secondary currents in river bends' by J. C. Bathurst, C. R. Thorne and R. D. Hey, *Nature* **269**, p. 504, line 2 in paragraph 6 should read . . . angle  $\phi$  to the longstream axis.  $\phi$  defines the vector of the . . .

# matters arising

## How did barium titanate particulates stick together in the Nebula?

MASUDA and Tanaka<sup>1</sup> in their recent letter have raised this question. Seeking explanation in the ferroelectric (FE) properties of BaTiO<sub>3</sub> we should ask now more specifically whether FE particles, similar to magnetic particles<sup>2</sup>, may provide preferred nuclei for accretionary processes.

A FE particle acquires charge densities ( $\sim 10^{-4}$  C cm<sup>-2</sup>) much greater than is found with ordinary electrostatic charging, for example, that arising from the termination of crystal structure in unsaturated and dangling bonds which become rapidly screened by adsorption. To produce the kind of homogeneous polarisation which FE particles develop at their Curie temperature  $T_c$  (393 K for BaTiO<sub>3</sub>) in an ordinary dielectric would require fields of  $10^6$ – $10^8$  V cm<sup>-1</sup>. The distorted surface layers observed on sub- $\mu$ m FE particles<sup>3</sup> indicate that the particles do not find it easy to screen their surface charges by adsorption or internal electrical conduction. Moreover,  $T_c$  of particles  $< 1 \mu$ m may exceed 700 K. We may thus expect the potential corresponding to a FE particle to be much greater than the 1–30 V considered feasible for normal electrostatically charged interplanetary grains<sup>4,5</sup>.

The potential energy of a small uniformly polarised BaTiO<sub>3</sub> crystal, represented by a doublet  $p_i$ , outside a complex formed by a collection of many uniformly polarised crystals and additional charge distributions corresponding to non-FE constituents, is determined by the normal component  $p_n$  at the surface of the complex. To determine the capture cross section<sup>6</sup> we consider a complex of radius  $r$  and surface polarisation  $p_n$  moving with velocity  $u$ . A doublet  $p_i$  with mass  $m_i$  and velocity  $v$  makes its closest approach at distance  $R$  from the centre of the complex and is captured in a grazing orbit. On the supposition of conservation of energy and momentum we obtain for the ratio  $K = (\pi R^2)/(\pi r^2)$

$$K \approx 1 + \frac{p_i p_n (1 + 3 \cos^2 \theta)^{1/2}}{4 \pi r^3 m_i v^2}$$

Taking  $p_i$  and  $p_n$  to be of the order of  $\approx 5 \times 10^{-5}$  C and  $v \approx 1.5$  cm s<sup>-1</sup> gives  $K \approx 5 \times 10^7$  for a 0.15  $\mu$ m particle.

The micrographs, presented by Masuda and Tanaka<sup>1</sup>, show a large number of small composite particulates with a narrow size distribution around 0.15  $\mu$ m and two conspicuous clusters of  $\sim 5 \mu$ m. If we were to interpret the latter as records of enhanced

capture cross sections of BaTiO<sub>3</sub> in the early environment within the nebula, then these would suggest enhancement factors between  $1.7$  and  $10^3$  and  $\sim 10^7$  depending on the size of the initial condensates.

While an enhanced capture cross section may explain why FE particles will stick together when available, it does not explain the high Ba abundances found in eucrites and in the Allende meteorite<sup>7,8</sup> as such. In view of the wide gap between the condensation temperature of  $\sim 1,680$  K and  $T_c$  those high BaTiO<sub>3</sub> concentrations which lie well above statistical fluctuations suggest selective spatial separation and enrichment. On account of the very high dielectric constant, even above  $T_c$ , the radiation pressure on BaTiO<sub>3</sub> condensates must have been greater than for most other particles of similar density and cross section. (Reflectivity coefficient for carbonaceous chondrites is  $\sim 0.04$ – $0.07$ , (ref. 8) for BaTiO<sub>3</sub>  $\sim 1$ .) For particles of  $\sim 0.1 \mu$ m the force due to radiation pressure outweighs by far the gravitational attraction. Assuming the latter to be balanced by the centrifugal force in the orbital motion, the spatial distribution of condensates will be determined primarily by the radiation pressure and the Lorentz forces due to a solar or interplanetary magnetic field<sup>10,11</sup>.

Considering conditions at 4 a.u. and assuming a moderate particle potential of 100 V in a uniform magnetic field of  $5 \times 10^{-5}$  gauss we obtain, in Table 1, for the forces due to radiation ( $f_R$ ), gravitation ( $f_G$ ) and Lorentz forces ( $f_L$ ) the following values for particles of 0.125, 1, and 5  $\mu$ m.

Table 1 Forces acting on FE particles

	0.125 $\mu$ m ( $\mu$ N)	1 $\mu$ m ( $\mu$ N)	5 $\mu$ m ( $\mu$ N)
$f_R$	$2.6 \times 10^{-14}$	$1.8 \times 10^{-12}$	$4.5 \times 10^{-11}$
$f_G$	$1.7 \times 10^{-14}$	$1.1 \times 10^{-11}$	$1.4 \times 10^{-9}$
$f_L$	$8.5 \times 10^{-13}$	$5.4 \times 10^{-12}$	$1.3 \times 10^{-11}$

We may thus infer that FE particles up to 1  $\mu$ m may settle out preferentially towards the inner part of the solar nebula. As particles aggregate into clusters of 5  $\mu$ m, however, the radiation pressure wins out and depending on growth and ablation, larger particles are thus likely to equilibrate at 4 a.u. or to be swept out to greater distances.

At distances  $\geq 1.75$  a.u. with grain temperatures  $< 300$  K a BaTiO<sub>3</sub> grain should be in its orthorhombic or rhombohedral modification. It would, therefore, be interesting to determine the crystal structure

of BaTiO<sub>3</sub> grains in the Allende meteorite. Moreover, the small dispersed particles as well as the larger clusters should exhibit FE polarisation and hysteresis<sup>11–13</sup> and it would thus be instructive to determine their *in-situ* Curie temperature. Structure and transition temperatures may give away further clues as to how BaTiO<sub>3</sub> grains came to be a vastly enriched constituent in the composite matrix forming the Allende meteorite.

## Diversity of deep-sea benthos

THE remarkable diversity of the deep-sea benthos is now well known, and Wolff<sup>1</sup> has contrasted two theories to explain this. One is Sanders<sup>2</sup> theory of niche specialisation, the other is Dayton and Hessler's<sup>3</sup> theory of biological disturbance, including disturbance by predators. One point that may discriminate between theories explaining diversity is that it seems that many deep-sea benthic forms have long life expectations and low reproductive rates<sup>1</sup>. I point out here that these life history characteristics are found in another quite distinct group of high diversity, which also lives in a habitat with very little seasonal change—tropical forest birds. Snow<sup>4</sup> reviews much of what is known of the population dynamics of such birds, particularly the fruit-eating ones. The life history seems to be characterised by small clutch size and yet a very high early mortality, particularly of eggs and nestlings, and a low mortality thereafter. This early mortality is caused by predators. Snow says "Once a bird has survived the early weeks of life, the tropical forest is a

much safer place to live in than the woods of temperate regions. Crises are rare: day after day passes in a peaceful, almost monotonous routine". Is it not possible that a similar pattern of life history mortality, high when very young, low thereafter, and a lack of seasonal changes, have enabled the evolution of high diversity both in the tropical forest and in the deep sea? If this is so, the critical specialisations would presumably be in minimising the early mortality in various ways, and small brood sizes may be a necessary part of these specialisations, by making detection by predators more difficult<sup>4</sup>. There would then be much less pressure for niche specialisation among the adults.

## Contemporaneity of late Cretaceous extinctions

THE dramatic extinctions at the end of the Cretaceous, both on land and in the sea, have long provoked speculation, but there is little direct evidence. Their existence is why the Cainozoic Era is distinguished from the Mesozoic, and in practice they are used in stratigraphy to make the Cretaceous–Palaeocene boundary. If the extinctions occurred at different times in different places, this practice would have to be revised.

Butler *et al.*<sup>1</sup> presented magnetostratigraphic evidence that dinosaur extinction in northern New Mexico occurred slightly later than the marine extinctions in central Italy. They seem to generalise this difference to all marine and terrestrial rock sequences, but this may be incorrect.

On the basis of extensive evidence of diverse kinds from Montana, we have been able to reconstruct ecologically the process of terrestrial extinctions there (refs 2–4 and unpublished). The time scale was ecologically very long but geologically very short ( $10^4$ – $10^5$  yr), just as in marine sequences<sup>5,6</sup>. The process, which affected marsupials almost as severely as dinosaurs but left the freshwater community entirely unaffected, was a protracted ecological succession which seems to have operated mainly by diffuse competition with placental and multituberculate mammals. This invading mammalian community<sup>7,8</sup> soon expanded worldwide to give rise to most of our familiar Cainozoic mammals.

We have predicted<sup>2,3</sup> that terrestrial extinctions farther south occurred later than those in Montana, but we were able to find<sup>2</sup> only two flimsy data relevant to

this prediction. Both were from South America and both supported the prediction. The extinctions in Montana were probably not the earliest, as dinosaurs occurred at least to about 75°N palaeolatitude<sup>2,9</sup> and we expect that dinosaurs disappeared here a little before they did near 50°N in Montana.

It would be a remarkable coincidence if the great marine and terrestrial extinctions did not have causal elements in common. We believe that these extinctions were in part synchronous but that the terrestrial extinctions moved south as the rapidly evolving placental mammals expanded out from their ancestral temperate community. Dinosaurs may well have survived into the Eocene in India<sup>2</sup>, which was an island during the critical interval.

## Do fatty acids inhibit gibberellin-induced amylolysis?

BULLER *et al.*<sup>1</sup> reported that fatty acids inhibit gibberellin-induced amylolysis in barley endosperm. Their experiments as described do not show if the effect is on induction of amylase by gibberellin, on amylase activity, or on resistance of starch to amylase attack, although they discuss results as "the exceptional efficacy of pentanoic ( $C_5$ ) and nonanoic ( $C_9$ ) acids in overcoming the effect of GA...".

Mitchell and Zillmann<sup>2</sup> showed that fatty acids increased flour and starch pasting ability, and some years ago I measured similar effects. In the Amylograph<sup>3</sup>, with the naturally occurring enzymes inactivated<sup>4</sup>, a wheat flour had maximum paste viscosity 1,205 Brabender Units (BU). Fatty acid additions (500 mg each to the mixture of 60 g flour and 440 ml water) gave the follow-

ing increases of maximum viscosity, confirming Mitchell and Zillmann's observations:  $C_6$ , 45 BU;  $C_7$ , 85 BU;  $C_8$ , 160 BU;  $C_9$ , 125 BU;  $C_{10}$ , 10 BU and  $C_{11}$ , 5 BU.

If the flour enzymes (including amylases) were not inactivated, then  $C_8$  fatty acid had remarkably greater effect. Adding 500 mg (58  $\mu$ mol per g flour, or 7.9 mM) increased viscosity from 495 BU to 975 BU. This effect for very low amylase activity suggests that fatty acid altered starch properties and made it more resistant to enzymatic breakdown. Commercial glyceryl monostearate (GMS) has a similar effect but GMS plus  $C_8$  acid was no more effective than one component, nor did glyceryl monocaprylate strengthen starch more markedly than equimolar amounts of  $C_8$  acid or GMS.

I suggest that fatty acids about  $C_8$  can make starch more resistant to amylase degradation. Thus the effect demonstrated by Buller *et al.* could be of fatty acid making starch more resistant to amylolysis rather than an effect associated with gibberellin.

PETER MEREDITH

Wheat Research Institute,  
DSIR, Christchurch,  
New Zealand

1. Buller, D. C., Parker, W. & Reid, J. S. G. *Nature* **260**, 169–170 (1976).
2. Mitchell, W. A. & Zillmann, E. *Trans. Am. Ass. Cereal Chemists* **9**, 64–79 (1951).
3. Meredith, P. *Cereal Chem.* **47**, 492–500 (1960).

BULLER AND REID REPLY—We have reported that saturated fatty acids of chain length around  $C_9$  are potent inhibitors of gibberellin-triggered amylolysis in embryo-free barley half-grains<sup>1</sup>. We are aware that the efficacy of these acids "in overcoming the effect of GA" might be due either to their interfering with some aspect of the production, activation or secretion of amylolytic enzymes or to their inhibition of the amylolytic enzymes themselves. We are now investigating the biochemical mechanism(s) of fatty acid action.

In experiments carefully controlled to eliminate fatty acid effects on amylase activity in our assay systems we have observed that the fatty acids of chain lengths  $C_7$ ,  $C_8$  and  $C_9$  at  $5 \times 10^{-4}$  M completely inhibit the release of amylase activity from gibberellin-treated barley aleurone layers. This suggests that the fatty acids can interfere, directly or indirectly, with amylase 'induction' or release.

Yet fatty acids can also inhibit the activity of amylolytic enzymes. Nonanoate ( $C_9$ ) at  $10^{-3}$  M reduces by about 60% (relative to a citrate control) the

rate of production of reducing equivalents from a solution of potato starch by a crude soluble 'amylase' prepared from germinated barley (N. Harris and J. S. G. R., unpublished).

Our results to date, therefore, suggest that fatty acids of chain length around C<sub>9</sub> inhibit both the production and the activity of amylolytic enzymes. Both effects undoubtedly contributed to our earlier observations<sup>1</sup>.

Meredith's suggestion that fatty acids might interact with starch, making it less susceptible to amylolysis, adds a further variable to an already complex problem. Any observed inhibition by fatty acids of amylolytic activity could be attributed either to a fatty acid-enzyme interaction or to a fatty acid-starch interaction as proposed by Meredith. We cannot yet assess the relative importance of the two effects in our assays, and we point out that even the experimental data presented by Meredith can be reinterpreted in terms of a fatty acid-enzyme interaction.

## An imbricate thrust model for Southern Uplands of Scotland

THE timing of the letter by McKerrrow, Leggett and Eales<sup>1</sup> is curious in that the model is not new. It was anticipated in concept by Mitchell<sup>2</sup> and in detailed demonstration by Fyfe and Weir<sup>3</sup>. In addition information given within the article includes details of the sequences seen along the British Gas pipeline, and a structural analysis from the Moffat area by Eales. The former is interesting although unexceptionable, apart from the fact that it sets aside without justification previous evidence that not all the Ordovician volcanics are of Arenig age<sup>4-6</sup>. The structural analysis is unsubstantiated but, more importantly, it ignores structural sequences already established from many other areas in the Southern Uplands and Ireland, which are supported by recent studies<sup>7,8</sup>.

The history of Cockburnland also requires clarification. Originally proposed<sup>9</sup> as the largely ophiolitic source for the Ordovician flysch of the Southern Uplands, it has been criticised as inadequate to provide the accumulated volume of sediment<sup>9</sup>. The

name was retained, but was used instead to designate the landmass uplifted in Llandovery times<sup>10</sup> south of the nascent Southern Uplands Fault, and now considered to represent the emergence of an evolving accretionary prism. Obduction of oceanic crust towards or over the Laurentian front<sup>11</sup> would create a sedimentary source adequate to provide the known volume of Ordovician flysch, thus dispelling the objection to an Ordovician Cockburnland. We consider that application of the name to the developing accretionary prism can be justified only by assuming geographical continuity with the remnants of the original structure.

Furthermore, the model prescribes progressive sedimentation of coarse clastics from north west to the south east. This must be an over-simplification, in that for at least part of the Llandovery the Moffat shale belt was bounded to north west and south east by thick sandy sequences<sup>12</sup>.

MCKERRROW, LEGGETT AND EALES  
REPLY.—The timing of our contribution was the result of work carried out in 1976 on new exposures in the British Gas pipeline. The model relating the structure of the Southern Uplands to contemporary subduction was first illustrated by Mitchell and McKerrrow<sup>1</sup>; this model was based, in part, on earlier work by Craig and Walton<sup>2</sup>, Toghill<sup>3</sup>, Kelling<sup>4</sup> and Fyfe and Weir<sup>5</sup>.

Our contribution did not imply that all the Ordovician volcanics in the Southern Uplands are of Arenig age. Those near Abington lie below Arenig cherts, while those at Coulter underlie Llandeilo cherts; the cherts in both areas may well be much younger than the basalts below them. In addition, there are other volcanics interbedded with greywackes (like those at Wrae

and Bail Hill), but these are not oceanic basalts.

The structural analysis (Eales, unpublished) was applied specifically to the incompetent Moffat Shale facies where it occurs at the base of major thrust sheets. It is only in this facies, with its classical graptolite faunal successions, that refined stratigraphy can be used as a basis for structural synthesis. Other local structural sequences (for example, Rust<sup>6</sup>; Weir<sup>7</sup>) are generally consistent with this analysis, but they lack detailed stratigraphic control.

Walton<sup>8</sup> gave the name Cockburnland to the emergent "chain stretching north-eastwards along the northern margin of the present Southern Uplands" which provide a source for the Llandeilo and Caradoc rocks of the area around Glen App. He also used the same name for the Llandovery landmass which provided sediment both northwards (to the Silurian of the Midland Valley inliers) and southwards (to the Central and Southern Belts of the Southern Uplands). The 'Cockburnland' shown in our contribution (Fig. 3) is the second of these two land areas. It is not clear whether the earliest Ordovician greywackes were derived directly from previously obducted ophiolites lying to the north of the Southern Upland Fault (as Walton and Weir suggest), or whether they were derived from previously accreted ocean floor volcanics and cherts on the inner trench wall.

Our model implies that most of the sediments in the Southern Uplands were deposited on the floor of (or on the margin of) the Iapetus Ocean. Even though coarser sediments occur in the Llandovery and Wenlock beds exposed in the Southern Belt of the Southern Uplands, this does not imply any south-east boundary to the 'Moffat Shale belt', it merely shows that coarser sediments were being deposited on the Iapetus Ocean at this time.

## Filling Bondi's place

PROFESSOR Sir Hermann Bondi, profiled this week (page 201), took up his post as chief scientist at the UK Department of Energy on 1 October. That the post he left at the Ministry of Defence has remained unfilled for a comparatively short while should not diminish concern over the way this and similar appointments are made.

Bondi's former post is the highest in government which any scientist can hope to achieve. Its holder has the stature to receive the most privileged information, and the access to offer independent advice, across the broadest range of issues, at the highest levels of government. To have it vacant longer than necessary is thus undesirable. Yet the Ministry of Defence has known of Bondi's departure for nearly five months—possibly longer.

The delay has a simple and not unreasonable explanation. Because the post is also the highest which can be occupied by someone from outside both political and civil service ranks, the appointee must be acceptable to those he will work with—service chiefs as well as ministers and civil servants. The choice will be further limited by the need for

a 'link man' with the scientific community who has standing and prestige and who is also willing to give up his job. And even when the right man is found, there remains the crucial matter of security clearance.

The question is whether such an important appointment, of such consequence for the public interest, should be made more openly even though—perhaps because—the number of candidates is so restricted. The argument against this is that to name names would subject potential candidates to considerable pressures in their existing jobs, and that the consequences of a failed security clearance would be fearfully embarrassing—all without much good being done. But this does not mean that public canvassing of names cannot work. Indeed, it works elsewhere, notably in the United States, where experience with it is admittedly far greater. The public interest aspect aside, the US system may even work better. If so, the question now is whether a change could be implemented smoothly in Britain without ending up with the worst of both systems. The trouble is, no one is involved in or even encouraging discussion of it. □

## New frontiers at Trieste

THE International Centre for Theoretical Physics (ICTP) at Trieste, dedicated to the support of physicists in the developing world, lives on several knife-edges. For one thing it relies on comparable contributions for its support from the international agencies UNESCO and IAEA and also on the continued financial goodwill of the Italian government and the City of Trieste. For another there are many, scientists, included, who wonder whether theoretical physics is a luxury that it is no business of the developed world to stimulate by means of courses at a very high level. Yet again, inevitably the quality of those who attend is much more variable than, say, amongst a group of students with a common background; thus the Centre will have more than its fair share of visitors who feel lost in its environment. And finally, there are certainly those who say 'if theoretical physics, why not experimental biology', and so on.

The Centre, under the guidance of Abdus Salam, has not, however, put up the shutters against criticism. Rather, it has been making moves to add new disciplines to its range of interests. Thus in the past couple of years it has held substantial courses on the teaching of physics at French-speaking universities in the developing world, on solar-energy conversion, on the physics of oceans and the atmosphere and, most recently, on the physics of the Earth. There is talk, also, of the possibility of a new experimental centre to be built on the Yugoslav/Italian border.

As the centre adds new peripheral interests to its core subjects of high-energy and nuclear physics, solid state physics and applicable mathematics, it finds itself closer to the tricky problems of science and society. Indeed the oceans and atmosphere course was stimulated by the Bangladesh floods, and the physics of the Earth course by the Friuli earthquake of last year which shook Trieste. Out of such courses can come politically relevant action, as happened last week. Students on the course were presented with lectures on earthquake-prediction research as practised in the United States, Soviet Union, Italy, China and

Japan. But the question arose, what should developing countries be doing about this? Many of the worst losses of life and property occur in the developing world; are such countries to wait supinely until systems are perfected elsewhere, and then be confronted with a very expensive package? Yet if not, most developing countries could not mount a major research initiative.

The need, then, is for a middle way which encourages scientists to keep in touch with developments and accumulate the necessary background information and which convinces politicians that there are human and economic benefits to treating the matter seriously. The centre, it emerged during discussions, could play a significant role in assisting technology transfer. The proposal was that ICTP, with its devotion to scientific excellence and its easy relations with scientists from a wide range of developing countries, should take a formal and special interest in ensuring that such scientists are kept fully in touch with developments in prediction and the assessment of seismic risk. ICTP already takes a similar special interest in solid state physics, a subject with relevance to the developing world.

This initiative should be widely welcomed. (The Editor declares an interest, having been involved in the discussions.) Of course there are international unions and associations which could also have performed this function to a degree, but satisfaction at the possible commitment of ICTP in this work will far outweigh any quibbles over who else could have done what.

In the longer run ICTP, in conjunction with UNESCO maybe, could possibly participate more actively in the raising of political consciousness on earthquake hazards. A model already exists in the team of examiners which occasionally emerges from OECD in Paris to visit a developed country and examine its science policy. A team of experts in earthquake protection could perform a similar role of persuading politicians to take their duties in hazard reduction seriously. □

The North American North (1)

# What strategy for development?

David Spurgeon in Ottawa summarises a Science Council report on the development of Canada's North

**L**ITTLE-KNOWN to the rest of the world, Canada is a country about which myth and misconception abound. Many people are especially ignorant of Canada's North, but that is scarcely to be wondered at, for so are Canadians themselves. And lately, many of the myths have been challenged from within, including the myth of self-sufficiency in energy and minerals. No less than the economic adviser to the Progressive Conservative party, James Gillies, has wondered about Canada as a technologically advanced nation and suggested that the country should return to reliance on selling its natural resources.

This orgy of self examination has also included some fundamental studies of the North, and the latest is a report from the Science Council of Canada. Called *Northward Looking: A Strategy and a Science Policy for Northern Development*, it is the result of 3½ years' preparation and sets out a strategy designed to bring more economic and technological self-sufficiency to the North, and a set of principles that should guide science policies for northern development.

But to set the stage, it tells Canadians a few facts about the part of their country—the largest part—that few of them have ever seen. The perspective bears repetition. Canada is the second largest country in the world, and the Yukon and the Northwest Territories together comprise 41% of its land area. As the report puts it:

Canada ranks 33rd among countries of the world in population. There is no settlement in 89% of our land area. In 1971, our average population density south of 60 degrees was 1,024 people per hundred square miles; for Nova Scotia, 3,867; for Ontario, 2,239. In the Yukon it was 9, and in the Northwest Territories, 3. Half of the people in the Northwest Territories and 60% of those in the Yukon live in *urban* environments. The northern part of Canada is mostly a lonesome place.

The North, says the report, is characterised by "small populations, a short growing season, permafrost, and long, cold, dark winters. The Extreme North and the Middle North are very different. The Extreme North is nearly uninhabited, has very little vegetation, continuous permafrost, ice-infested waters all or nearly all year, and very little precipitation. The Middle North has discontinuous permafrost, is heavily forested, more accessible, and is the

focus of resource exploration at this time. It is the region where the large majority of northern residents now live".

The people of the North, as distinctive as their environment, present problems for demographers. They move over large areas, there are cultural and linguistic differences, and many settlements are relatively isolated. Demographic statistics are thus more crude than elsewhere in the country. No accurate population figures exist on Métis and non-status Indians in Canada. The Native Council of Canada estimates 750,000 people on the basis of three Métis for each status Indian (295,215 in 1971 in all Canada). The total population of the North is about one million. Compared with the rest of Canada, they are younger and have received less formal education. There is a larger component of native people (especially in Saskatchewan, Manitoba, Quebec, and the Northwest Territories), and larger proportions of the population are engaged in forestry, fishing, trapping, and mining than in Canada as a whole.

Large communities are uncommon in the North: in 1971 only 29% lived in settlements of over 10,000, compared to 65% in Canada as a whole. Within the North, a community of more than 2,000 is an urban environment. Most of the immigrants settle in the larger centres: more than 70% of the non-natives live in the five largest communities of the Northwest Territories—Yellowknife, Inuvik, Hay River, Fort Smith and Frobisher Bay.

Epidemiological data indicate that health standards in the North are lower than in the rest of Canada. And although the birth rate has now begun to level off, the age structure of the native population resembles that of Latin America or Africa more than the rest of Canada. Twenty per cent of the inhabitants of the Northwest Territories speak neither English nor French, there are several native dialects, and in the Mackenzie River Valley and Delta, six native languages. "There is not really just one North in Canada", says the report. "The diversity of the North is as striking as its cold".

## Historical overview first

To study this area, the council undertook a historical overview and case

studies of northern development. The work was synthesised in a discussion paper, which then served as the basic document for seminars and to solicit opinion from more than 100 people involved in northern affairs. All this led to the framing of the final report. The chairman of the Science Council Committee on Northern Development, W. H. Gauvin, notes in an introduction that the process covered a period when many important issues were emerging: the OPEC oil embargo, land claims by natives in the James Bay area, the first drilling from artificial islands in the Beaufort Sea, preparations for northern pipelines and extraction of oil from the sands and so on.

It is against this background that the report's recommendations must be set. It notes that the recent history of the North has been the product of two conflicting trends: the thrust toward large-scale exploitation of natural resources, and the desire to continue traditional resource harvesting activities such as fishing, hunting and trapping, which would lead to development based on smaller scale, locally controlled projects.

"The Science Council believes that both major trends should be accommodated in a *strategy of mixed development*", says the report. "Such a strategy would press for more economic and technological self-sufficiency for the North. Activities that can be logically defined and controlled would be favoured over those which tend to increase political and economic dependence, the need for welfare, or other undesirable social conditions. This means an emphasis on relatively low capital, decentralised, and small scale development".

The objectives of northern development espoused by the Science Council are similar to those expressed by the federal government: to promote the welfare of northern people, to maintain and enhance the regenerative capacity of the environment, to give renewable resource development a higher priority, and to encourage economically viable non-renewable resource projects that are in the national interest and will benefit—or at least not harm—northern residents and their environment.

This strategy of mixed development will require greater sensitivity to traditional patterns of land use, says the report. It also says it will involve extracting mineral resources more slowly than some "major participants" may desire. Ironically, shortly after the report appeared, the Energy Minister, Alastair Gillespie, was proposing encouraging exploration by the multinational oil companies by offering them tax cuts. The report emphasises

that the land has special significance for many native northerners, and needs to be valued in terms of its capability to meet a variety of needs not measurable in monetary terms.

The report also calls for greater recognition of the value of public participation in projects concerning the North. "The right of people directly affected by a project to have something to say about it is becoming more widely accepted. . . . In the North, in fact, complaints about adequate *consultation* have been so frequent that the question of *participation* itself is only now being raised. To pursue successfully the strategy of mixed development, there must be more than informing, educating, and consulting northern people about the needs of the rest of Canada for a certain project".

The report lays down four principles that should guide policies for northern development:

- Technological sovereignty: the ability of Canadians to control, direct and benefit from technological enterprises deemed essential to the country.
- Life-style flexibility: the need to allow opportunities for choices of life style.
- Maintenance of the regenerative capacity of the land.
- Comprehensive and balanced assessment and monitoring of large and small projects.

These four principles, it says, should govern the choice of all new research and development initiatives in the North.

Technological sovereignty has become a buzz word at the Science Council. The reason for applying it to the North is that there, as elsewhere, "Canadians and Canadian science and industry tend to place undue emphasis on foreign expertise and foreign consultants". The report says that foreign-owned firms tend to perform the research that has the greatest potential for long-term payoffs in their home countries.

In offshore Labrador, for example, where several companies are searching for oil and developing the expertise necessary for that environment, Canadian firms have participated in the data collection phase, but they have had very little to do with planning and design of production and transportation facilities. The nature of research activity in Canadian resource-related industries, then, tends to resemble the resource extraction industries themselves. That is, with few exceptions, Canadians provide the raw materials, but the control of the operation, the processing and, hence, long-term benefits tend to flow out of the country.

In order to support the proposed strategies for northern development the Science Council makes a number of proposals. One is that universities should play a greater role in the solu-

tion of northern problems. In spite of the efforts of the universities of Alberta, Saskatchewan, McGill, Chicoutimi, Laval, Memorial (in Newfoundland) and others, most northern research is now performed by industry and government. Canada needs a cadre of researchers not dependent on contracts from interested parties, the report says. The Science Council urges that funds for northern research be re-allocated so that grants are emphasised over contracts, and that the granting councils provide funds for logistic support over and above other costs, because northern research is costly.

In addition, the Council urges the establishment of a University of the North to provide the focus for northern research. This university should concentrate on such areas as resource management and systematising resource inventories, and should promote the innovation of northern technologies. Native peoples should play a central role in the choice of

research topics and in undertaking research. Funding should be primarily from the federal government, and the university at first would give only graduate degrees.

The report emphasises the need for an inventory of renewable resources, and other data on the North, and the need for improved communications. There is also a need for coordination and exchange of the information that would come out of a northern data bank system, particularly among those who fund northern research. "It is intolerable that Members of Parliament should regularly report difficulties in gaining access to technical and scientific information relevant to political decision-making", it says.

In the past, most scientific exploration of Canada's North has been carried out by scientists of other countries, and much of the North's development has been for the benefit of others. If the Science Council's recommendations are acted upon, that era may end. □

The North American North (2)

## Money or energy problem?

Jeff Carruthers in Ottawa examines the most expensive private capital project ever undertaken, the AlCan gas pipeline

CANADA and the United States have together decided to build an all-new gas transmission system to carry Alaskan natural gas more than 5,000 miles to markets in North America's industrial heartlands in the North and West. The planned pipeline can be described in many ways, all of them large. The cost alone will be at least \$10,000 million. Ultimately the system might also transport smaller gas reserves from Canada's nearby petroleum fields in the Mackenzie Delta and Beaufort Sea region of the western Canadian Arctic, to its own consumers in central and eastern Canada.

From a financial perspective, the Alaska Highway pipeline project is almost certainly the most expensive private capital project ever undertaken. Economists and bankers generally agree that financing could stretch Canadian and American money markets to their limit, especially if the inflation and cost over-runs that have plagued other recent North American energy projects (such as the trans-Alaska oil pipeline and the mammoth James Bay hydroelectric project) push costs for the Alaska Highway project to the \$15,000 million or \$20,000 million that some experts fear.

From a technical viewpoint, the problems to be encountered in the northernmost areas in Alaska and the Canadian Yukon Territory are considerable, but at the same time not regarded as insoluble. The key issue is whether they can be resolved within the time and cost parameters agreed to by the two governments. A frigid and dark climate prevails during the winter construction months. Gravel and water are difficult to find in places for construction. The permafrost, where materials hard as rock in below-zero temperatures can turn to soup if thawed, and where a phenomenon called 'frost heave' can literally lift a pipeline out of the ground if it is intentionally chilled through water-rich permafrost soils, presents its own problems. And an ecology that in many places is poorly understood needs protecting.

Economically speaking, Canada regards the pipeline project almost as a godsend, calculating that it could provide upwards of 100,000 man-years of direct and indirect employment for an economy facing rising unemployment, a worsening balance of trade and a damaging rate of inflation. In fact the

project is widely regarded as much as a make-work scheme as a vital (if costly) way of developing urgently-needed energy supplies.

### Energy initiative

Yet it is the energy initiative inherent in the pipeline project which puts the Alaska Highway cooperative venture into its proper perspective. For \$10,000 million the United States hopes to connect gas reserves of 22-24 trillion cubic feet (TCF) in Alaska's Prudhoe Bay oil fields to markets in the lower 48 states. Assuming all of that gas is available—and there is some controversy about this already, based on fears that extraction of the gas could lower the recovery of associated (and more vital) crude oil—it would be sufficient to fill one year of current US gas demand.

Canada, which is hoping the pipeline can be connected later to some 5.2 TCF of gas in the Mackenzie Delta, would be able to fill two years of its current demand with its northern gas from the Delta. Ironically, perhaps, Canada is slated to export more natural gas from already-connected fields in southern Canada to the United States during the next decade than it hopes to connect in the western Arctic—and this is gas costing considerably less than Alaskan and Delta gas (the best estimates at present are that the Alaska Highway pipeline will deliver northern gas to southern markets for between \$3 and \$4 a thousand cubic feet, assuming no major cost over-runs for the pipeline project).

Critics of the pipeline include church groups, energy conservation groups, and environmentalists and northern native groups. They have argued that Canada and the United States do not really need the extra gas and that the adoption of adequate energy conservation techniques nationally could probably do more good for the state of the two nations' energy than any mammoth project. They have managed to focus national attention on a stark reality: that replacement energy for wasted existing energy resources in Canada is costing so much to develop on a per unit basis that even supposedly resource-rich countries like Canada cannot continue to rely on the non-renewable fossil fuels indefinitely.

If anything, the Alaska Highway pipeline underlines the growing belief that the availability of money is rapidly becoming more critical than the avail-

Building the trans-Alaska oil pipeline

ability of new energy resources, especially as the new resources grow more and more remote either geographically, as with Arctic gas and oil, or technologically, as with Canada's vast oil sands deposits.

### Two competitors

This relatively new concern about finance, which ultimately translates into energy costs to consumers, was one of the key factors in the two governments' selection of the Alaska Highway project over two competing gas transmission projects.

One rival consortium had proposed a pipeline from the oil and gas fields across the environmentally-sensitive North Slope (with the Alaska Wildlife range) to the Mackenzie River Delta, then up the Mackenzie River valley in the Northwest Territories to the province of Alberta, and then into the United States and central Canada. This proposal, by Canadian Arctic Gas Pipelines Ltd, a US-dominated consortium, was rejected in Canada on socio-economic and environmental grounds, even though it was believed to be technically superior to the Alaska Highway project. Approval of the project would have meant opening up the relatively lush Mackenzie Valley and would have risked confrontation with militant native groups, which are still trying to settle aboriginal claims with the Canadian government for much of the area.

The Arctic Gas project, as it was called, was the front-runner until a few months before the final government decision. A historic northern inquiry by a provincial Supreme Court judge, Thomas Berger, had been launched by the government to study the impact of such a development on the North generally and on the Mackenzie Valley specifically. Berger's report dealt a death blow to the Arctic Gas project when it suggested that the native way

of life for northern Eskimos and Indians would be ruined should the pipeline proceed within the decade. Berger looked more favourably on the Alaska Highway project, in part because a highway to Alaska had already disrupted that part of the North and because the natives were already more integrated into a southern style of life.

Other factors helped to kill the Arctic Gas project. The small Canadian gas reserves in the western Arctic, for example, did not justify an immediate Canadian commitment to a joint pipeline with the United States (the Alaska Highway project, by contrast is intended initially to serve only the United States). Arctic Gas also said it needed government guarantees to be able to finance its slightly-larger project—guarantees neither government was willing to provide. In addition, 'frost heave' and winter construction problems were more severe along the Mackenzie Valley route (the consortium would have had to provide 24-hour-a-day artificial lighting and artificial snow to construct the most northerly portions). Finally, the Arctic Gas project probably wouldn't have been Canadian controlled.

In the last analysis, the Arctic Gas project was an engineering and technical solution, based also on geological prospects along the route. But it failed to be sufficiently flexible to cope with non-technical matters, including its impact on native northerners, on Caribou herds, and on the ecology of a major river valley and a delta in the Arctic—not to mention political matters such as Canadian nationalism. To add further to the irony, the Arctic Gas proposal was studied to a much greater extent than the Alaska Highway project, so that more of the problems associated with it were known and widely publicised by its opponents in the media and before regulatory

review bodies.

Another petroleum industry consortium, preparing officially to propose the construction of an even longer and more technically difficult gas pipeline from the High Arctic of Canada (Melville Island initially) to southern markets, is keenly aware of this danger of being too prepared. The Polar Gas consortium, as it is called, is proposing a step-by-step government review in which the broad economic, social and environmental issues are dealt with first, preferably to produce some sort of initial government approval. Then more studies would be done and more money spent on the technical aspects of getting a 42-inch gas pipeline safely to the mainland, across marine trenches tens of miles wide and as much as 1,500 feet deep. The Polar Gas project is expected to cost even more than the Alaska Highway project, and to tap 10 to 15 TCF of gas for Canadian and possibly American markets.

### Second project

The other project defeated by the Alaska Highway pipeline was the El Paso scheme to transport the Alaskan gas in liquified form by tankers to the west coast. The US government decided that a pipeline across Canada was more economical and involved less risk because a well-proven technology was being used. Since that decision earlier this year a number of Canadian companies (including PetroCanada, the national petroleum company, and Alberta Gas Trunk Line Company Ltd of Calgary, one of the two founders of the Alaska Highway pipeline consortium in Canada) have been studying the feasibility of using special ice-strengthened liquified natural gas tankers to transport High Arctic Islands gas from Melville Island to markets along the eastern seaboard. The project, if it is ever pursued, will initially move only 250,000 cubic feet a day, compared to more than 2,000 million cubic feet a day to be moved along the Alaska Highway pipeline starting in 1983.

In allowing the Alaska Highway pipeline to cross Canada, the Canadian government has insisted that the Canadian portions be Canadian controlled and has accepted the promises by private industry (the Foothills Pipelines Ltd consortium) that Canadian content in the Canadian portions would exceed 90% for goods and services. The government is assuming that in a few years the go-ahead will also be given to a lateral pipeline to the Mackenzie Delta, and space has been reserved in the pipeline for this Canadian gas.

The US government has even agreed to have its gas consumers pay for a

substantial portion of the lateral pipeline to the Mackenzie Delta, on the condition that cost over-runs in the Canadian sections of the main pipeline are kept below 35%. As a further incentive to keep costs under control, and with the nightmare cost over-runs associated with the TransAlaska oil pipeline still fresh in mind, the two governments plan to tie approved return on equity for the private participants to the success in minimising costs.

The US Congress has recently given legislative approval for the project. Legislation should be introduced in the Canadian parliament before the end of the year which will also establish a single monitoring agency to ensure that environmental and native impact is minimised and to ensure that safety standards are met.

Finance is the next major hurdle, with \$8,100 million due to be raised in US capital markets and \$1,700 million in Canada. The first official attempts at financing should take place late next year. And should private financing in North America fail, the pipeline consortium is expected to seek government assistance in Washington and Ottawa before trying to tap European and other foreign money markets.

The pipeline project promises major business and major technological challenges for many key industries in Canada and the United States—steel, construction equipment, valves and turbine compressors, ditchers and welding machines, engineering and consulting services. It should therefore come as no surprise that the Canadian government hopes to use the Alaska Highway project as a lever for convincing more foreign companies to start working and manufacturing in Canada, using more Canadian talent instead of just Canadian raw resources.

On the planning boards in government offices, the Alaska Highway project is only one of a long list of expensive and increasingly technically difficult energy projects, including tidal power, oil sands extraction plants, heavy oil extraction and up-grading plants, more northern gas pipelines, LNG tanker transportation schemes, nuclear power (using the CANDU system developed in Canada), hydroelectric developments (including the use of DC transmission for long-distance power movement), offshore exploration, and coal gasification plants.

As with the Alaska Highway pipeline, the uncertainty surrounding these projects relates more to the availability of financing than of technical expertise. And the Canadian government says it is willing to invest in equity in such projects if necessary, if only to make sure the money is available. □

## SPACE

# Meteosat's turn

*Judy Redfearn reports on Europe's latest satellite*

METEOSAT, Europe's first satellite devoted entirely to watching the weather, was scheduled for launch this week from Cape Canaveral into a geostationary orbit 35,900 km above the equator. But a valve in the second stage of its Thor Delta 2914 launcher developed a leak last weekend. NASA has announced that the launch will be delayed, until it can replace either the launcher or the valve.

When Meteosat finally arrives in its planned orbit it will take images of the earth's surface and cloud cover both in the visible and infrared which will be used by European meteorological services to improve their long range weather forecasting. The idea to build a geostationary meteorological satellite was included in the European Space Agency's (ESA) optional application programme in 1971.

Meteosat will, in fact, be only the

first of several European meteorological satellites. The second is already approved and should be ready for launch in the early 1980s and subsequent ones are under consideration. Meteosat therefore has a dual role: it is partly pre-operational, designed to prove a satellite system, but it is also an important scientific satellite in its own right.

From its position in space, Meteosat will relay back to earth meteorological data on most of Europe, the whole of Africa and the Middle East. Together with four other geostationary satellites positioned symmetrically above the equator, two American (Goes), one Soviet (GOMS), and one Japanese (GMS), it will make weather monitoring of the whole globe possible between latitudes  $+50^\circ$  and  $-50^\circ$ . The five satellites will be taking part in the first global experiment, running from the end of 1978 to the end of 1979, of the Global Atmospheric Research Programme (GARP).

The Japanese GMS was launched last July, and the USA already has

three Goes satellites up—two it will use and the third it is storing in space as a spare. But the Soviet Union's satellite, due for launch in about a year's time, is unlikely to be ready because of technical difficulties. NASA's precaution in keeping a stand-by ready may yet save the first global experiment, though no decision on how to replace the Soviet satellite has been taken.

A feature distinguishing Meteosat from other satellites is the way in which the data it generates is processed. Because of the enormous data volume—two images every half hour—all processing must be done in real time. The facility set up especially to do this and to disseminate information to the users is at the European Space Operations Centre (ESOC) at Darmstadt. After the images have been corrected for distortion at Darmstadt, they are relayed back to the satellite and then on to the users.

Should Meteosat itself fail, however, there will be another chance. As with the Orbital Test Satellite, ESA took out insurance for \$16 million to cover costs of a replacement launcher and integration of a second satellite. □

## SWEDEN

# Fälldin's energy puzzle

*Wendy Barnaby, in Stockholm, updates nuclear developments in Sweden*

CONSERVATION groups in Sweden recently succeeded in stopping a long-disputed application to mine the bulk of Europe's uranium. The application, which the mining company LKAB had previously withdrawn and re-presented taking more account of environmental considerations, was to mine 200 tons of uranium a year for ten years from an area about 350 km south-west of Stockholm, where the uranium deposits are estimated to be the largest in the West in the price range of \$10–15 a pound (1968 prices). The local government body used its right to veto any project involving such widespread damage to the environment which, it maintains, is rich in cultural treasures. A spokesman for the company said that it would now begin discussions with the government and that this could lead to a research and development project going ahead, with a small amount of mining to sustain it.

But the action taken over the LKAB application is only one of the pieces, a relatively small piece, of the country's

energy puzzle. There are many others that have yet to be fitted in. At the centre of the government's difficulties is the interpretation of the law which specifies the conditions under which the building of reactors may continue. Under the law, the owners of any reactor being planned or under construction must present the government with concrete proposals of the 'completely safe' storage of unprocessed waste or of highly-radioactive waste, if the spent fuel is to be reprocessed. Reprocessing agreements must also have been concluded before the government gives permission for the reactor to be built.

Although the owners of Barsebäck 2 and Ringhals 1 and 2 reactors have concluded agreements with the French Cogema company for reprocessing spent fuel, there is some doubt that the government will recognise the agreements as fulfilling the conditions of the law. This is because of a report prepared jointly by a committee of Cogema's trade unions, employers and safety representatives, which demanded that security at the plant be improved to meet national and international standards and itemised 47 points on which improvements in security and operations in general could be made.

Critics here say that the spirit of the Swedish law demands reprocessing agreements which will guarantee workable, reliable reprocessing. The reactor owners maintain that their responsibility under the law stops with the signing of legal agreements, and that the security matters to be taken care of at the plant are Cogema's business, not theirs. They are happy, they say, to trust the Frenchmen's technical abilities to solve the problems at their end. Overshadowing the entire deal is a query about the American government's attitude. There is no guarantee that the Americans, who supply Sweden with its enriched uranium and can veto the export of spent fuel from Sweden for reprocessing, will allow it to go ahead.

The government must soon decide which interpretation of the law it is to favour. It has given one reprocessing agreement to the state Nuclear Power Inspectorate for comments, and these are expected to be published late in November. The government's decision is expected in December.

December will also see the first of two 'security reports' being presented to the government by the nuclear power industry. The first one will deal with storage of reprocessed spent fuel, and will maintain that safe storage is technically possible. The second, to

*(continued overleaf, page 202)*

## PROFILE

Chris Sherwell on Sir Hermann Bondi

## An effective use of oil

HERMANN BONDI followed an auspicious precedent in British government when he left the Ministry of Defence to take over as chief scientist at the Department of Energy seven weeks ago. Before him, only Solly Zuckerman and Alan Cottrell had ever held the position of chief scientist in two separate departments of state—though they moved from Defence to the Cabinet Office, and in the days before the Rothschild reorganisation gave the institution its present form.

The appointment itself, when it finally came, was no surprise to anyone who had bothered to read the newspapers. But there was a gap before it was announced while the minor storm generated by the departure of Bondi's predecessor, Walter Marshall, subsided. The gap which Bondi himself left at Defence remains, and though names are being canvassed, no indication of who is in the running is officially available.

Bondi came to Energy with a remarkable record. Schooled in Vienna, where he was born 58 years ago, he went to Trinity College, Cambridge, and then became what was bureaucratically called a 'temporary experimental officer' in the Admiralty from 1942–45. In 1954, after holding a Trinity fellowship and lecturing for the best part of eight years, he was appointed to the chair of mathematics at King's College, London. Then in 1967 a leave of absence allowed him to become director general of the European Space Research Organisation. He stayed until 1971, when he became chief scientist at the Ministry of Defence.

The experience at Defence colours his approach in his new post. He regards the issue of nuclear proliferation as particularly important, for example. But as he puts it, "Things have to be looked at with a certain order of priority". Short term problems like proliferation must be checked before long term ones can be tackled. If the world is going to blow itself up first, he is not too worried about, say, the threat of a 'greenhouse effect' from over-use of fossil fuel.

Not that he has no views on the greenhouse effect. He says the US National Academy of Sciences report published earlier this year has been read as "more definite" than he reads it. If atmospheric oxygen comes from living plants making use of carbon

dioxide, he asks, and rising carbon dioxide levels can encourage plants to grow and so stabilise the rise, might not preservation of the most active plants in the best parts of the world be better than a restriction on the use of coal? It is a question for the long term, Bondi says simply, which will be of no interest at all unless we attempt to ensure our survival in the short term.

He is reticent about giving his own views on such immediate issues as maintaining the breeder option or Britain's choice of reactor. He stresses that energy as a whole, and not just nuclear power, is capital intensive and expensive, the turnover of the energy industries being about the same as the defence and education budgets combined. As he sees it, R&D in alternative energy technologies must be fostered in case conventional sources become unacceptable, unavailable or too expensive, but the judgment of likely fuel costs is complex.

One economic consideration which puzzles him is the effect of the oil price increase four years ago. The developed countries initially responded by saying they would maintain their economic growth and replace oil with nuclear power. That led to colossal predictions for the growth of nuclear power, says Bondi. "But the calculations were completely bogus". The fuel crisis stopped growth, and nuclear forecasts slumped. Instead of energy prices rising relative to other things, inflation and a lack of growth caused fuel costs in many fields to become a smaller share of the total than they were. "So if I'm asked whether a project for an alternative energy source would become economic if the real price of fuel doubled, I must ask if engineering costs will go up equally disproportionately, and whether we'll be back where we started".

As Bondi sees it, a rise in fuel costs, rather like a failed harvest in developing countries, has to mean a substantial drop in the standard of living. But developed countries have been totally unwilling to accept this. Is there an appreciation of this within government? "I preach it", Bondi replies with a smile. He is as aware as anyone of the problems governments face, as he shows when he allows his thoughts about costs to stray to current issues. The difficulty

Sir Hermann Bondi

when it comes to choosing a reactor or investing in alternative energy sources, he says, is not really a lack of money, but spending it sensibly and responsibly—not whether to purchase, but what to purchase.

So how should a chief scientist be seen? "Like any scientist", Bondi says, "the chief scientist has a particular standing when he gives a judgment on scientific matters. But he wouldn't be a responsible citizen if he didn't have a judgment on other matters as well, although he has no more claim to authority on these than anybody else". Bondi regards the important element in the chief scientist's task as "making clear what the scientific issues are, within the context of other questions".

He is clear why he came to Energy. First of all he was asked, and he has an appetite for change. Another attraction was that it was controversial. But there is a third aspect, which has to do with his time at Defence. He enjoyed his time there, he says, and they enjoyed having him. He rejects completely any suggestion that they wanted to see him go. But the contribution of somebody from outside springs from the person's different background and different way of thinking. "He treads water for a while, learns to understand the issues and how to handle the machine. Then he can make a distinct contribution. But after some years he loses the advantages an outside background is supposed to confer".

He has now applied the lesson to himself. At Defence, he says, he had become part of the furniture. "I was with my fourth secretary of state, my third permanent secretary, and my sixth chief of defence staff". Continuity has its own contribution to make, he says. "But I'm not convinced that I was bringing to it as much as I had done, say, two years ago, though"—and this with a twinkle—"I knew very well how to put a drop of oil into the machine". He now has more oil, and a smaller machine.

come next spring, will deal with storage of unprocessed waste, and will no doubt be optimistic too.

election is, according to Fálldin, a distinct possibility.

With Fällidin's position hardening, the government will have to deal with applications expected from the State Power Board early next year to load the Ringhals 3 and Forsmark 1 reactors. The Prime Minister has already refused to allow Ringhals 3 to be loaded once, saying that the State Power Board had not fulfilled the security conditions, and he has recently said that if it is loaded he will resign. March will be no less momentous a month. President Carter is then expected to enlarge on his proposal to store Sweden's (and other countries')

unprocessed spent fuel in the USA. Fälldin's coalition partners are reportedly willing to accept Carter's invitation, but Fälldin is doubtful about releasing spent fuel to storage facilities which have had their own technical troubles. Also in March the Energy Commission is to present its report on alternative energy futures to Parliament. Whether it will be able to come up with some viable transition to environmentally-benign energy production is as yet unknown. But unless it does, Fälldin's tactics seem bound to end in either a devastating loss of face for his party, or in his own resignation. □

which the somatostatin could be chemically cut off.

How important, in general, is this technique? And specifically, how important is the artificial production of somatostatin? The main point

[illegible]

There is no doubt that this latest achievement, which is due to a team led by Herbert Boyer of the City of Hope Medical Center in California, is an important technical step forward. Insulin genes were successfully transplanted into bacteria earlier this year, but it has so far proved impossible to get the bacteria to produce insulin from them. Boyer's team, instead of isolating and transplanting a real gene, synthesised a nucleotide sequence corresponding to the sequence of 18 amino acids that go to make up somatotropin. That gave them an 'artificial gene' which they have not only inserted into bacteria, but persuaded the bacteria to decode into somatostatin.

Boyer and his colleagues have been reluctant to disclose details of their experiments because the work is still unpublished. But it seems that the 'artificial gene' was inserted into a plasmid containing part of the bacterial *lac* operon—a package of bacterial genes that controls the production of the enzyme  $\beta$ -galactosidase. The somatostatin gene was placed in the middle of the  $\beta$ -galactosidase gene, where the two genes would be transcribed together under the control of the *lac* promoter gene. The resultant RNA was apparently translated into a hybrid protein from

about the technique is that it shows that it is possible to induce bacteria to make animal gene products. The demonstration that this can be done with synthetic genes may have two important consequences. First, there is mounting evidence that the genes of higher animals are different from those of bacteria in that they contain regions of DNA that do not code for the final protein. Since it is unlikely that a bacterium would be equipped to cope with such discontinuous genes, it is important to know that a simple coding sequence can be used instead of an actual gene. Second, there are now many cases in which

what is needed for medical purposes is not the natural protein but a specific analogue of it. If bacteria can be made to produce the original from an artificial gene, then they can presumably also work on an artificial gene coding for an analogue.

There are also two important limitations on the technique, however. First, it is only practical to make synthetic genes for relatively small molecules, and small molecules are not very difficult to synthesise by traditional means. Whether genetic engineering will eventually prove the cheaper way it is hard to gauge. Second, the particular method Boyer's team used to clip the somatostatin out of the hybrid protein is not generally applicable. It depends on the fact that the bacterial protein contains a specific chemical group that is not present in somatostatin. However, it is present in most proteins.

Somatostatin itself is unlikely to be very widely used for clinical purposes. It inhibits the release of the hormones glucagon, thyrotrophin, prolactin, gastrin and insulin. Because of its inhibition of hormones that act against insulin, it has been clinically tried in cases of extreme insulin-resistant diabetes (less than 5% of diabetics). But because of its effects on other hormones, and the fact that it inhibits the aggregation of platelets and may thus predispose to haemorrhage, it is most unlikely to find more widespread application. Attempts have been made to find analogues with more specific action, but they have so far failed and it may be that all the diverse actions of the neurohormone depend on the same chemical feature.

At this stage, therefore, the remarkable achievement of Boyer and his collaborators remains an advance in principle rather than in practice.

## IN BRIEF

## Reactor choice soon

Consultations held by Britain's energy minister, Mr Anthony Wedgwood Benn, on the country's choice of thermal nuclear reactor, are drawing to a close now that most submissions from interested parties on the subject have been received. A decision is expected before Christmas.

The latest submission on the issue has come from the Trades Union Congress (TUC), representing Britain's labour movement. Its fuel and power industries committee wants the immediate ordering of an AGR station with another later, and a major effort to work up a detailed and acceptable PWR design before a decision on a third station is made. The committee also supports the construction of a demonstration breeder reactor and of expanded reprocessing facilities at Windscale.

Last month the country's two main electricity boards, the CEBG and SSEB, submitted their views to the Department of Energy. The department has also published virtually in full the report of an assessment of the three reactor types under consideration by the National Nuclear Corporation.

## ACORD members named

The chairman of the UK Science Research Council (SRC), Professor Geoffrey Allen, has stepped into another appointment recently vacated by his predecessor at SRC, Sir Sam Edwards: membership of the Advisory Council on Research and Development for fuel and power (ACORD). Dr Joseph Gibson, the board member for science at the National Coal Board, joins ACORD as NCB representative.

ACORD, with 10 longer-serving members drawn entirely from industry,

will shortly have to take a serious decision: how to advise Benn on the Severn Barrage schemes for tidal power, which will help to energise Britain but may radically alter the ecology of her greatest estuary.

## SA's nuclear optimism

With the controversy over South Africa's nuclear intentions still volatile, the president of the South African atomic energy board, Dr Ampie Roux, has said that if the United States cuts off supplies of nuclear fuel for the Koeberg nuclear station north of Cape Town, his country's uranium enrichment process could ensure supplies within a few years of the station's start-up date in the early 1980s. Dr Roux also said that South African uranium output would increase to make her the West's second largest producer after the United States.

SOCIOBIOLOGY seeks to explain that human social behaviour has a genetic, and, therefore, an evolutionary background, which has long been obvious for other orders of animals, especially the *Hymenoptera*. Against the acceptance of this concept is the fact that many people dislike being compared with monkeys and object even more to being told that they resemble insects.

I am becoming increasingly nervous about my behaviour being the result of millions of years of evolution, a conclusion I have to reach if I embrace the teachings of sociobiology. The thought puts me on my mettle; I should try not to let my genes down. My behaviour is a rather poor illustration of a progressive evolutionary process, but the sociobiologists say that social evolution may indeed be occasionally reversible. Other nagging questions assail me: should I obey my impulses because these promptings are the result of inherited patterns of mental processes? Or should I suppress these impulses in the biological interests of benefiting my group? Or should I try to shape up so as to be a survival machine for my genes, which, says Richard Dawkins, "swarm in huge colonies, safe inside gigantic lumbering robots, sealed off from the outside world . . . their preservation is the ultimate rationale of our existence . . ."?

In any case, the subject of sociobiology merits attention because Dick Lewontin dislikes it, and he is a man of strong convictions on important issues. Moreover, perhaps sociobiology could be an interesting chal-

lenge to the pan-selectionist school of evolutionists, who object to the proposal, made by the so-called 'neutralists', that amino acid replacements in homologous proteins of different

## On sociobiology

THOMAS H. JUKES

species are often changes that have no effect on the properties of the protein, but are incorporated by genetic drift. The neutral model also says that many mutations are deleterious and are rejected by natural selection, and a few become accepted by a species because they are advantageous.

The opposing view states that each amino acid in a protein must have a unique survival value in the phenotype of the organism. Would ethologists extend this general principle to

behavioural phenomena? Perhaps the idea of neutral hereditary changes could be extended to explain certain habits that have little to commend them, or it could even account for harmless quirks that have no particular bearing on our survival as a species. A leading sociobiologist reassuringly says that only about 10% to 15% of human social behaviour is genetically based, but I don't know what has led him to such a quantitative assessment. The same author says, "The hypothalamic-limbic complex automatically denies . . . logical reduction by replacing it with feelings of guilt and altruism". In other words, our emotions, which are part of our inheritance, prevent us from reaching conclusions based on logic. This is a facile way of disarming criticism, of course.

It seems to me that sociobiology aggravates its opponents by the ingenuity with which it produces explanations to make observations fit a theory. To a considerable extent, pan-selectionism has done the same by finding an adaptive advantage for each phenotypic trait. We are told that even the hair-pattern on our backs was selected by evolution in our ancestors to help shed the rain as they crouched on the branch of a tree during a tropical storm.

Perhaps those who disbelieve and spurn sociobiological teachings may be responding to a genetic trait. The struggle against pre-ordained fate could in itself have a survival value. This struggle may include the rejection of theories that tell us we are in the grip of determinism imposed by our genes.

## Gametes of malaria parasites

from F. E. G. Cox

It has always been one of the major aims of parasitology to maintain parasites in culture and to minimise as far as possible the use of human subjects or laboratory animals. A year ago, the possibility of growing all stages of the human malaria parasite, *Plasmodium falciparum*, in culture was brought a step nearer when Trager and Jensen (*Science* **193**, 673; 1976) described the continuous cultivation of the blood-inhabiting asexual stages of this parasite in a simple medium. The next stage in the malaria life cycle is the development of gametocytes (the stages that infect mosquitoes) from the asexual stages in the blood and in this issue of *Nature* (page 240) Carter and Beach describe how this can be achieved *in vitro*. The early stages of *P. falciparum* that invade red cells can develop into either asexual stages, a process which takes about 18–24 h, or into gametocytes which takes about 10 days (Smalley *Nature* **264**, 271; 1976). It was the development of the asexual stages that Trager and Jensen achieved. Carter and Beach observed that in cultures of *P. falciparum* maintained in

Trager's medium, without the dilution that is usually carried out, obvious immature gametocytes were present after the expected 10 days. The problem was how to bring these stages to maturity. This was achieved by adding 50% human serum instead of the usual 10% to the cultures and after 8 days morphologically mature gametocytes were present. The next step was to confirm that these gametocytes were functionally mature by transforming them into gametes and this was done by suspending the gametocytes in foetal calf serum at pH 8.0 or human serum at pH 8.2. Trager's culture medium requires a pH of 7.3–7.4 for the growth of asexual stages so it is essential to change the pH in order to bring about these transformations.

The gametocytes and gametes produced by Carter and Beach look normal in every way and occur in similar proportions of male to female (1:3.5 compared with 1:4) to those in humans. There is no reason to doubt that they should be able to infect mosquitoes. This means that it should now be possible to complete the asexual and sexual cycles of *P. falciparum* without the need for a mammalian

host. It will next be necessary to grow the liver stages of the parasite *in vitro* but this should not present any insuperable difficulties. In the meantime, numerous experiments on the infectivity of *P. falciparum* to mosquitoes have become possible.

The question as to how long the gametocytes of *P. falciparum* are infective to mosquitos is an interesting one. Hawking, Wilson and Gammage (*Trans. R. Soc. trop. Med. Hyg.* **65**, 549; 1971) calculated that gametocytes were produced in a circadian pattern and that they would be infective for only a short period. Bray, McCrae and Smalley (*Int. J. Parasit.* **6**, 399; 1976) on the other hand, found no evidence for a circadian rhythm and Smalley and Sinden (*Parasitology* **74**, 1; 1977) showed that, in humans, gametocytes are infective for 2 weeks or more. The observations of Carter and Beach suggest that gametocytes can mature to gametes for several days at least and this supports the observations of Smalley and Sinden. The technique itself will be useful in resolving problems of this kind in future. It should also be possible to test the effects of drugs on gametocytes—a hitherto relatively unexplored field. □

F. E. G. Cox is Professor of Zoology at King's College, London.

## Coevolution of *Calvaria* and the dodo

from Robert M. May

MUTUALISTIC associations, in which two species interact in such a way that each benefits from the presence of the other, are fascinating for several reasons. For the theoretician, they are increasingly shedding light on the interplay between the long sweep of evolution and the immediate dynamical effects of population interactions (for example, King, Gallaher & Levin *J. theor. Biol.* **53**, 263; 1975). For the naturalist, and even for the pure aesthete, they provide some of nature's

richest wonders: the homes and food that many tropical acacias supply for their protective ants; the nectar supplied by flowering plants as the price for pollination; the almost erotic coupling between many tropical orchids and their obligate bee pollinators.

One class of mutualistic interactions we should all be grateful for is that between fruit-producing plants and the animals that disperse their seeds. The fleshy part of the fruit is the cost the plant pays to induce animals (typically birds) to eat the fruit; the associated benefit is that the seeds, having taken some time to pass through the animals,

are spread widely. The fruits we eat are the direct or horticulturally-improved outcome of such coevolutionary cost-benefit calculations.

In systems of this kind, a major design problem is producing a seed that can survive the passage through the digestive tract of the fruit-eating animal. A partial answer is to speed the passage of the seed; hence the mildly laxative effect of many fruits (notably prunes).

All this brings us, rather surprisingly, to the dodo. This large, flightless bird was endemic to the 700-square-mile island of Mauritius. Its disappearance by 1681 is probably the most familiar

Robert M. May is the Class of 1877 Professor of Zoology at Princeton University.

The Dodo (*Raphus cucullatus*)

example of an extinction directly attributable to man: 'The Dodo used to walk around/And take the sun and air./The sun warms his native ground—/The Dodo is not there!/The voice which used to squawk and squeak/Is now forever dumb—/Yet may you see his bones and beak/All in the Mu-se-um.' (Belloc, *The Bad Child's Book of Beasts*, Dover reprint, 1961; see also Hachisuka, *The Dodo and Kindred Birds*, Witherby, 1953). Stanley Temple (*Science* **197**, 885; 1977) has drawn attention to the fact that the large monoecious tree *Calvaria major*, which according to historical records was once abundant and exploited for lumber on Mauritius, also seems to have undergone a trauma dating back to the dodo's demise. There were by 1973 only 13 *Calvaria major* trees surviving in the remnant native forests of the island, and all 13 were estimated to be more than 300 years old. No younger specimens are known to exist, even though the surviving trees produce well-formed, apparently fertile seeds each year. None of these seeds now germinate naturally, even if planted in nursery conditions.

Temple notes that, although there are several examples where the elimination of a plant species has been deleterious for an associated animal species, the *Calvaria*-dodo system may be the first documented instance where disappearance of the animal partner has doomed a mutualistic plant species. The mechanism suggested by Temple is that the seed inside the *Calvaria* fruit developed a coat (endocarp) thick and strong enough to resist crushing in the powerful gizzard of the dodo. As a result, 'these specialised, thick-walled pits could withstand ingestion by dodos, but the seeds within were unable to germinate' without the coat first being battered and abraded by the stones in the dodo's gizzard.

In support of this hypothesis, Temple observes that the *Calvaria* fruits are today consumed by some frugivorous animals, notably a parakeet and a flying fox, but that none is large

enough to eat the fruit whole, and thus disperse the seed. The dodo was large enough, and therefore it was presumably the customer for whom the tree designed its fruit. There is fossil evidence that dodos ate *Calvaria* fruit. Furthermore, measurements of the crushing forces generated by the stones in the gizzards of granivorous birds from several taxonomic groups (ranging in body weight from 0.8 to 3.2 kg) give a formula which, when applied to the 12-kg dodo, suggest crushing forces of around  $10^4 \text{ kg m}^{-2}$  in its gizzard. *Calvaria* pits are strong enough to withstand these forces, but only just: Temple suggests that once the pit had been sufficiently abraded to reduce its size by 30%, the seed would be crushed. But by then some of the seeds would have passed through the dodo, albeit after a battering which would weaken the endocarp and facilitate germination of the infant plant within.

As an experimental test of his ideas, Temple force-fed *Calvaria* seeds to turkeys, whose gizzards generate crushing forces around  $4,000 \text{ kg m}^{-2}$ , fairly close to those inferred for dodos. Of 17 seeds, seven were crushed. The remaining 10 were either regurgitated or defaecated, some after up to 6 days. These 10 seeds were planted in nursery conditions, and three subsequently germinated. Temple concludes that 'these may well have been the first *Calvaria* seeds to germinate in more than 300 years.' □

## More evidence for a closed Universe from QSOs

from T. Kiang

FURTHER evidence that quasars (QSOs) can provide information on the nature of the Universe comes from the work of Chinese astronomers. Their work complements the recent observation of the ultraviolet spectrum of the QSO 3C273 by Davidsen *et al.* (*Nature*, **269**, 203, 1977; *News and Views* **269**, 195; 1977). The Chinese astronomers have constructed Hubble diagrams for various subsets of radio QSOs using a different luminosity indicator from Davidsen *et al.*, but come to essentially the same conclusion.

It has long been realised that one of the best means to decide whether the Universe is open (the declaration para-

meter  $q_0$  less than  $\frac{1}{2}$  and the Universe expanding for ever) or closed ( $q_0$  greater than  $\frac{1}{2}$  and the Universe eventually falling back on itself) is by means of the Hubble diagram, in which the redshift  $z$  is plotted against the apparent magnitude  $m$ . (The redshift is the reddening of the light from stars and galaxies due to their recession). But the relations predicted by different cosmologies become distinguishable only when the redshifts extend beyond the present limit ( $\sim 0.5$ ) for the galaxies. That is why the discovery of QSOs with much higher redshifts brought high hopes. However, these hopes were soon dashed, for the first Hubble diagrams for QSOs looked like pure scatter diagrams, showing hardly any trend whatever. Subsequently, some astronomers took the view that the QSO redshifts are 'intrinsic' and not 'cosmological' at all.

Most astronomers, however, held to the view that these redshifts are at least largely a distance effect, and that the featureless Hubble diagram is due to the sample being a mixture of many different types of object. In support of this view, Setti and Woltjer (*Astrophys. J. Lett.* **181**, L61; 1973) showed that, if the sample is restricted to QSOs with steep radio spectra, then the scatter is much reduced, and a trend of the expected kind can be seen. Similarly, Stannard (*Nature* **236**, 295; 1973) found that the same thing happens if only objects with flat spectra are considered. But in these diagrams, there is still a large dispersion, which is attributed to spread in luminosity within each type. Further progress thus awaits the identification of some 'luminosity indicator', and that is where J. A. Baldwin's recent demonstration of the correlation between  $L\alpha$  intensity and continuum luminosity comes in (*Astrophys. J.* **214**, 679; 1977). Using the equivalent width of  $L\alpha$  as a luminosity indicator, Davidson *et al.* identified five quasars with  $z$  between 2.3 and 3.4 which are presumably as luminous as 3C273 at  $z = 0.158$ . Here at last is a Hubble diagram for objects of a limited luminosity range, and this fact is probably more significant than the particular result they obtained ( $q_0 \sim +1$ ) which the authors are quick to point out, critically depends on what one assumes for the galactic reddening in the direction of 3C273.

The diagram by Davidsen *et al.* is not the first one of its kind. In a paper in the Chinese journal *Acta astronomica sinica* (**17**, No. 2, 134; 1977; English translation in *Chinese Astronomy*, **1**, No. 2, in the press) an entirely different luminosity indicator was used and Hubble diagrams for

T. Kiang is a Professor in the Dublin Institute for Advanced Studies and is at the Dunsink Observatory, Castleknock, County Dublin.

various subsets of radio QSOs constructed, leading to a value of  $q_0 = +1.38$ . The authors of this paper are Fang Li-zhi, Zhou You-yuan, Cheng Fu-zhen and Chu Yao-quan from the University of Science and Technology of China—names quite unknown in the West.

Confining their attention to those QSOs with resolved radio components, these authors propose that the linear separation  $D$  between the components be used as a luminosity indicator. (They eventually back up this suggestion by actually deriving a value for the rate of change of the optical luminosity with  $D$ ). Since  $D$  is not directly observable, a rather subtle statistical argument was used in getting plausible estimates of  $D$ . Starting with observed angular separation  $\theta$  and redshift  $z$ , and assuming a distance-redshift relation  $r = r(z)$ , one calculates the projected distance  $r\theta$ , which differs from  $D$  by a projection factor  $\sin \psi$ , say. Now, in an isotropic distribution of directions in space,  $\sin \psi$  is concentrated near its large end value of 1. The authors argue that what one can do here is to take only those quasars with  $r\theta$  values at or close to the observed maximum  $r\theta$  value at the given  $z$ , and then simply set  $D = r\theta$  for such objects. In this way, from a sample of some 90 radio quasars with known  $\theta$  and  $z$ , they picked out 26 for which such indicative values of  $D$  can be assigned. Separate Hubble diagrams were then constructed for various ranges in  $D$ .

Rather tight correlations consistently appear in these diagrams, which typically have 10 data points and a scatter of about 0.6 magnitudes. But the linear regression coefficient of  $m$  upon  $\log z$  departs significantly from 5, which means that the classical Hubble relation  $r(z) \propto z$  is no longer valid. In a self-consistent series of calculations, the authors then found that, in order to recover a slope of 5, the regression analysis must be made between  $m$  and  $\log(z - 0.19z^2)$ . This is equivalent to saying that the correct distance-redshift relation is of the form  $r(z) \propto z - 0.19z^2$ , and that is how the formally precise value of  $q_0 = +1.38$  was obtained, because in relativistic models, the coefficient of  $z^2$  here is equal to  $\frac{1}{2}(1 - q_0)$ .

Although the true uncertainty in this determination must be very much larger than the formal value implies, it is probably not as large as in the derivation by Davidsen *et al.*, because the sample is larger and the sample points more evenly distributed. The two results complement each other in that one deals with flat-spectrum objects and the other, mainly steep spectrum objects. They agree in saying

that the Universe is probably closed.

On the other hand, because of consistent failure in detecting sufficient mass in one form or other, astronomers in recent years have become more and more disposed towards the opposite alternative of an open Universe—this, for example, was very much the general feeling in the recent Symposium on Large-Scale Structure of the Universe, held at Tallinn, Estonia.

The determination of  $q_0$  tacitly assumes that no change of luminosity has taken place in time. Hence the challenge now is to find a physically plausible model of luminosity evolution that will account for both a low mass density and a high value of  $q_0$ .

The evaluation of  $q_0$  is only one of several results obtained by Fang Li-zhi *et al.* Many astrophysicists may find their result that the optical luminosity of a quasar decreases by 2.3 magnitudes for every megaparsec increase in the linear separation between its radio components to be even more important.  $\square$

## Magnetic moments of short-lived nuclear states

from P. E. Hodgson

A NEW method of measuring the magnetic moments of nuclear states of very short lifetime has recently been developed by N. Benczer-Koller and colleagues at Rutgers University, and some preliminary results have just been reported at the recent conference on nuclear structure held in Tokyo in September. They have applied the method to several isotopes of iron, nickel and zinc and obtain results that are important for testing nuclear models.

In this method, a 72 MeV beam of  $^{32}\text{S}$  ions hits the target material, which is deposited on a  $2 \text{ mg cm}^{-2}$  layer of magnetised iron backed by  $10 \text{ mg cm}^{-2}$  copper, as shown in the figure. Some of the target nuclei are excited, and these recoil through the iron and stop in the copper, where they decay by gamma emission. The energy of the gamma ray identifies the state of excitation of the recoiling target nucleus.

The gamma rays are detected in coincidence with the  $^{32}\text{S}$  ions recoiling in the direction opposite to that of the incident beam. This ensures that the knocked-on target nuclei pass perpendicularly through the magnetised iron so that the length of their path in that

material is accurately known. As the target nuclei pass through the magnetised iron their magnetic moments precess and the angle of precession is measured by the rotation of the angular distribution of the de-excitation gamma rays,  $\Delta \theta \sim g \int B dt$ . The value of  $\int B dt$  and the constant of proportionality are determined by a subsidiary experiment using ions of known magnetic moment, so that a measurement of  $\Delta \theta$  enables  $g$  to be found. It is sufficient for practical purposes to use an empirical relation describing the dependence of  $B$  on the velocity of the ion; this is quite different from the theoretical relation, but this lack of understanding of the process does not affect the determination of the magnetic moments.

As an example of the results obtained, the magnetic moment of the lowest  $2^+$  state of  $^{54}\text{Fe}$ , that has a mean life of only 1.4 ps, is found to be  $1.68 \pm 0.38$ . Magnetic moments have also been determined for the lowest  $2^+$  state of  $^{58}\text{Fe}$ , and for the same states of four isotopes of nickel and four isotopes of zinc. In some cases the magnetic moments were already known from other work, and the new and old values are in good agreement.

This method has many advantages over those used previously. The high magnetic field inside a ferromagnet enables the magnetic moments of states with lifetimes in the ps region to be measured, whereas the methods using laboratory magnetic fields are limited to states with lifetimes in the ns region. Since the ion is moving rapidly through the magnetised iron and does not stop there the results do not depend on the rate of energy loss at low velocities. This is a major source of uncertainty in the methods in which the ions come to rest in the iron. Furthermore,  $\Delta \theta$  is independent of the lifetime of the ion providing it is sufficient for the ion to pass through the magnetised region.

The magnetic moments of excited states can be calculated from the shell model, and provide a searching test of its validity. The new results for the nickel isotopes disagree with shell model calculations that take no account of core excitation, but are in good accord with newer calculations that include  $f_{7/2}$  core excitation.  $\square$

## Epiphyte or parasite?

from Peter D. Moore

It is not difficult to define the difference between an epiphyte and a parasite; the former depends on another organism simply for support whereas the latter exploits its host in a manner which is normally beneficial to the parasite but detrimental to the host. Neat definitions, however, are not always easy to apply in complex field situations. Take, for example, the relationship between the robust, brown, fucoid alga *Ascophyllum nodosum*, which is abundant in the intertidal zone of most of the more sheltered shores around the British Isles, and the small red alga, *Polysiphonia lanosa*, which is almost invariably associated with it. The red alga adheres strongly to its host, since its thallus actually penetrates the tissues of *Ascophyllum*. Where the biomass of the host is greatest, there one finds the greatest density of *Polysiphonia* also. Here is a perfect situation in which the epiphyte/parasite debate can be staged.

One can see certain advantages in the epiphytic habit in this type of algal community. Elevation during immersion provides obvious benefits, for the mass of floating fronds of the brown alga, buoyed up by air bladders, must cast a considerable degree of shade upon any bottom-dwelling algae. At the same time, close association with *Ascophyllum* could make life more comfortable during the periods of immersion when extremes of variation in temperature, relative humidity, salinity and light intensity would be dampened by the presence and protection of a mucilaginous mass of limp fronds. Simple epiphytism would not, therefore, be an unreasonable expectation in such a circumstance.

The possibility that *Polysiphonia* is more than an innocuous passenger demands examination, however, for the attachment of the red algal thallus to its host seems remarkably secure for a species association which is found only where wave action is very slight. An examination of the anatomy of the attachment region by Rawlence and Taylor (*Can. J. Bot.* **48**, 607; 1970) showed that rhizoids of the 'epiphyte' penetrated deeply into the thallus of *Ascophyllum*.

Citharel (*C. r. Séanc. hebdom. Acad. Sci. Paris, Ser. D*, **274**, 1094; 1972) used a physiological approach to the problem, considering that, since no true epiphyte would take up metabolites

from its host, any demonstration of transport of reduced carbon from the brown alga to the red would provide grounds for an accusation of hemiparasitism. Citharel chose glutamic acid as the most likely vehicle of carbon transport, since this is the most abundant free amino acid in the *Ascophyllum* thallus. He injected  $^{14}\text{C}$  labelled glutamic acid into the thallus of *Ascophyllum* and observed its accumulation in *Polysiphonia* within 12 h. He concluded that, contrary to the opinion of such algal authorities as Fritch, *Polysiphonia* should be considered a partial parasite. The demonstration of such a transfer does not, however, necessarily infer that the red alga is dependent upon *Ascophyllum* as a carbon source, indeed Harlin and Craigie have argued that it is not (*J. Phycol.* **11**, 109; 1975).

A further complication has now been brought to light by translocation experiments by Turner and Evans (*New Phytol.* **79**, 363; 1977). They supplied  $^{14}\text{C}$ -labelled bicarbonate ions to *Ascophyllum* tissues and studied translocation of the label to parts of the plant isolated from the initial supply, and also into tissues of *Polysiphonia* attached to the host plant. In this way they hoped to overcome two possible objections to the experiments of Citharel, first that the labelled compound supplied by him was not in fact the product of photosynthetic activity in *Ascophyllum* and, second, that transport of metabolite could occur by secretion into the surrounding medium and reabsorption by *Polysiphonia*, or even by way of the mucilage surrounding the species. The outcome of Turner and Evans' experiments demonstrated that there was no translocation of the label in the tissues of *Ascophyllum* either with or without attached *Polysiphonia*. This means that if *Polysiphonia* is acting parasitically it can only exploit the cells in the immediate vicinity of the rhizoids, for the lack of translocation in the host will preclude any wider effect of such parasitism. They also demonstrated that *Polysiphonia* was able to accumulate  $^{14}\text{C}$  from labelled bicarbonate in the surrounding medium, confirming the independent carbon assimilation of the red alga, but they further showed that the 'epiphyte' was able to take up and use exogenously supplied labelled glucose.

So the question of whether or not *Polysiphonia lanosa* is a true epiphyte of *Ascophyllum nodosum* still remains unanswered. What is now clear is that if *Polysiphonia* depends upon its host

for more than support in a physical sense, it will be limited in its success by the lack of movement of metabolites in the host tissue and will be dependent on a local exploitation of cells or the absorption of materials secreted into the surrounding medium. As Turner and Evans point out, however, one cannot be sure that carbon is the sole object of any parasitism which occurs. Perhaps some other element is being sought, or even an organic growth factor. □

## Indo-Pacific drums reviewed

from a Correspondent

THE drums or croakers are fishes of very great commercial importance throughout tropical seas especially in shallow regions and where large rivers join the sea. They derive their common names from their habit of making loud noises of one kind and another; indeed it is claimed that native fishermen of South-east Asia only set their nets when their leader has heard the fish approaching the area. Because of their economic importance fishery workers in various countries have made numerous studies of their biology and aspects of their life history, and some have attempted taxonomic studies to establish some kind of phylogeny as well as a valid nomenclature. Notable amongst these was the work of Y. T. Chu, Y. L. Lo, and H. L. Wu, *A study of the classification of the sciaenoid fishes of China, with descriptions of new genera and species*, Shanghai Fisheries College, 1963, with a short English summary. Chu *et al.* produced a work of fundamental importance in which they placed considerable emphasis in classification on the structure of the otoliths and the swimbladder. Their synthesis proved to be a major landmark in understanding this group of fishes although necessarily it was largely confined to Chinese waters (where their commercial importance is very great).

However, their work has now been amplified and refined by a major revision, *The sciaenid fishes (croakers or drums) of the Indo-West-Pacific* by

*Johnius (Johnieops) dussumieri* (Cuvier) (Cuvier *Le règne animal*, 1840).

Peter D. Moore is a Senior Lecturer in the Department of Plant Sciences at King's College, London.

*Johnius coitor* (Hamilton *An account of the fishes of the Ganges*, 1822).

Ethelwynn Trewavas (*Trans. zool. Soc. Lond.* **33**, 253; 1977). Trewavas has expanded the area covered by major revisionary studies quite logically to include the less well known, but equally important, Indian Ocean species. Much of the new synthesis is founded on the form and structure of the swimbladder and otoliths for, having extended knowledge of these two organs, Trewavas finds them well found as major characters.

The degree of development of the swimbladder is a fascinating study and six main types are identified among the Indo-Pacific species. At its least elaborate the swimbladder is a simple large gas-filled sac with no appendages. Relatively few species (mostly Atlantic in their distribution) possess this form. Other types have diverticula running from the anterior end of the swimbladder and variously directed backwards or forwards (in one group running forwards into the head to underlie the skull), but in the subfamily Otolithinae the swimbladder is decorated with paired series of between 9 and 53 diverticula, mostly elegantly branched. In one tribe, Collichthyini, within this subfamily the diverticula are so developed that posteriorly their limbs enwrap the viscera, a situation which is paralleled in a distantly related West African family.

The large size of the otoliths of the sciaenid fishes is well known, both to science and to folklore (a necklace made of otoliths of a drum was found in a Californian Indian archaeological site), and names such as Otolithinae used within the group indicate that they have long been accepted as characteristic. Trewavas has extended the previous application of this feature to the taxonomy of the group, describing several new types and rationalising the nomenclature of the parts of the sagitta used by previous workers.

The net result of the analysis of otolith and swimbladder structure as

well as conventional taxonomic methods, such as fin ray, vertebra and scale counts, and morphological differences, is to produce a fundamentally important taxonomic work. In all, 65 species are recognised, grouped in 27 genera and 10 tribes. Each species is adequately described, with diagnostic

characters singled out, and basic synonymies are presented, with brief discussion on the synonymy. Keys are provided to all taxa as are diagnoses of families and genera. In total it presents fisheries workers in the Indian and West Pacific Oceans with a basic source for the identification of these important food fishes, one which was badly needed to judge from the synonymies presented.

It is peculiarly apt that these fishes which are well known for their sonic abilities have now been classified basically by the highly specific complex patterns of the swimbladder and the otolith and inner ear. It is generally accepted that the former is a sound-producing organ, of quality in this case, while the latter is concerned with sound reception. Living as they do in shallow tropical seas, especially in the clouded waters close to and within estuaries, the sciaenids have developed a sensitive auditory system which enables them to keep together and presumably to distinguish each other from other related species. □

## Animal migration at Tübingen

from Michael A. Bookman

A Symposium on Animal Migration, Navigation, and Homing was held in Tübingen, FRG from 12–20 August, 1977, in celebration of the 500th anniversary of the University of Tübingen.

ALTHOUGH the Sun can be used by many animals as a source of compass information, the ability to form a bright image on the retina and simultaneously derive accurate bearings without retinal damage remains puzzling. J. D. Pettigrew (California Institute of Technology) presented an interesting model linking the avian pecten oculi to solar orientation. Light scattered from the Sun's image on one edge of the retina would be interrupted by the pecten, which would cast a well-defined linear shadow over the temporal fovea adjacent to the image of the horizon. Peripheral imaging of the Sun prevents serious retinal damage while information is relayed to orientation-selective edge detectors in the visual wulst of the brain. With the potential for precise determination of the Sun's trajectory, some people were undoubtedly reminded of the 'rejected'

theories of bicoordinate solar navigation. An ingenious camera device that can be mounted on a pigeon's head to record the free-flying line of sight was described by K.-L. Köhler (Fürth, FRG). Investigation of orientation strategies with such a technique may aid the experimental evaluation of Pettigrew's model.

The sensory capabilities of homing pigeons were further reported on by M. L. Kriethen (Cornell University), J. D. Delius and J. Emmerton (Ruhr Universität, Bochum) and M. A. Bookman (Massachusetts Institute of Technology). In the laboratory, pigeons have demonstrated sensitivities to polarised light, ultraviolet light, small changes in barometric pressure, infrasound, and magnetic fields. Conditioning and electrophysiological experiments suggest that regional specialisation of the retina may optimise perception of polarised light. Sensitivity to ultraviolet light seems to result from the non-absorbance of the pigeon optical apparatus. L. J. M. Leask (Clarendon Laboratory, Oxford) proposed that the retina may also be involved in the detection of magnetic fields by a process of optical pumping and anisotropic decay of triplet states. Improved characterisation of magnetic responses, such as those by W. Wiltschko (Universität Frankfurt) with

Michael A. Bookman is in the Department of Psychology at the Massachusetts Institute of Technology.

migratory birds, will help in the formulation and testing of possible sensory mechanisms. The influence of magnetic fields on orientation was further documented by C. Walcott (State University of New York, Stony Brook), who reported on the persistent disorientation of pigeons released near natural magnetic anomalies. The extent to which many of these sensory capabilities are made use of in navigation is unknown, although hypotheses abound.

The role of wind-carried odours in pigeon homing was discussed by F. Papi and S. Benvenuti (Università di Pisa), K. Schmidt-Koenig and J. Kiepenheuer (Universität Tübingen), and R. F. Hartwick (James Cook University, Queensland). Most investigators acknowledged that in some circumstances odours could provide directional cues; however, most data do not support a central role for odours in pigeon homing. In a later discussion, W. T. Keeton (Cornell) reasoned that just as a hierarchy of redundant cues seems to supply compass information, a similar hierarchy is probably used to obtain map information. Therefore, research should not aim to uncover 'the' navigational scheme, because several schemes are likely to be used in different conditions.

Odours, however, clearly occupy a central role in the spawning of salmon. A. D. Hasler and A. Scholz (University of Wisconsin, Madison) described a remarkable experiment in which hatchery-raised salmon were exposed to chemically scented water for 1 month before their release into Lake Michigan. During the subsequent spawning season, small streams were artificially scented with the same compounds. Imprinted salmon were then recovered in large numbers from the appropriately scented stream.

The sensitivity of marine sharks, skates, and rays to voltage gradients on the order of  $0.01 \mu\text{V cm}^{-1}$  was described by A. J. Kalmijn (Woods Hole Oceanographic Institute). In the laboratory, these fish oriented to magnetic fields, presumably by responding to local electric fields induced by swimming through the magnetic field. Theoretically, fish could monitor natural voltage gradients found within ocean currents to obtain compass information and determine the direction of water flow.

In experiments with hatchling sea turtles, M. Mrosovsky (University of Toronto) demonstrated that movement from the nest to the water's edge is governed by a phototropic response to an integrative right-left balancing of retinal and tectal stimulation. L. C. Ireland (Oakland University, Rochester) used ultrasonic transmitters to track hatchling turtles on the initial portion of their maiden ocean voyage.

As yearlings, the turtles reach distant feeding grounds. He concluded that the initial directional stimulus was simply 'away from land', which perhaps represented an extension of nest-to-water movement.

Whether migratory birds are capable of true bicoordinate navigation or predominantly utilise only simpler forms of compass orientation remains controversial. T. C. and J. M. Williams (Swarthmore College) reported that successful migrants moving between North and South America seem to maintain a Southeast heading during their entire autumn migration, and would therefore not require a bicoordinate system. S. A. Gauthreaux (Clemson University, South Carolina) observed inland daytime flights of nocturnal migrants which are felt to correct for night-time drift. These flights suggest that some nocturnal migrants may actually navigate during the early daylight hours. A new release and tracking procedure for migratory birds using balloons and radar was developed by S. T. Emlen and N. J. Demong (Cornell). Although complex, this technique combines experimental control with near-natural flight conditions. Initial experiments showed that sparrows were able to select meaningful headings when released under cloud layers that obscured celestial cues. □

## A hundred years ago

### Bees killed by Tritoma

In a friend's garden here where there are quantities of Tritomas or "red-hot-pokers," hundreds of bees have been this year destroyed by them. The honey produced by the flower is very abundant, and the bees enter the tube of the corolla to get at it; but the tube, which is only just large enough at the mouth, tapers gradually, and so the bee gets wedged in and cannot extricate itself. I saw numbers so caught, some in the fresh flower, while others remained in the completely withered and decaying blossoms. Perhaps it may be due to the fine warm days we have had this autumn, inducing the bees to work too late after our native honey-producing flowers have been destroyed by the wet and frosts; or is it a regular thing which happens every year? If so bee-keepers should discourage the Tritoma, or set to work to select varieties with flowers large enough not to kill their bees.

ALFRED R. WALLACE

From *Nature* 17, 15 November, 45; 1877.

## Plasma lipoprotein structure

from Angelo M. Scanu

A workshop on Lipoprotein Structure was held at the University of Chicago on 8-9 October, 1977.

DURING the past 10 years, many studies have been carried out on the structure of circulating lipoproteins, relying primarily on physical and chemical techniques. The workshop provided an assessment of the current state of knowledge on the subject.

The discussion on small-angle X-ray scattering was focused mainly on the low-density lipoproteins (LDL), where controversy still exists on the state of organisation of their surface components. The recent studies by V. Luzzati *et al.* (Gif-sur-Yvette, France) have led investigators to postulate the existence of 'bumps' or 'spikes', which were attributed to protein units protruding from the surface of the particles. The investigations of P. Laggner *et al.* (Graz, Austria), in turn, although yielding essentially similar X-ray results, were interpreted as being compatible with a surface having no convolutions. The organisation of the LDL core also came under sharp scrutiny. There was agreement on the presence, in this core, of cholesteryl esters and triglycerides in varying proportions; the concentric smectic lamellar organisation of the cholesteryl esters suggested by the studies of D. Atkinson and G. Shipley (Boston), was disputed, however, by Luzzati, who proposed an alternative organised micellar structure without, however, giving details. Agreement seems to exist on the notion that triglycerides influence the core organisation of cholesteryl esters; this view appears well documented by the results of studies on the LDL of animals with hyperlipidemias secondary to the administration of cholesterol-supplemented dietary fats.

Contrary to the rather extensive studies performed with small-angle X-ray scattering, the work on plasma lipoproteins carried out by neutron diffraction (H. B. Stuhmann, FRG) has been comparatively modest. The validity of the method was recognised, however, and further applications were anticipated with suitable replacement of some of the LDL constituents by their deuterated counterparts. An elegant study of the naturally occurring quasi-crystalline egg yolk lipoprotein system was presented by L. Banaszak (St. Louis University, St. Louis), who has reconstructed a two-fold symmetry model from electron micrographs of negatively-stained preparations.

Differential scanning calorimetry is proving its usefulness in the study of plasma lipoproteins. A systematic study of the thermal behaviour of LDL, HDL, and related systems was reported by D. Small (Boston), who obtained information on the phase behaviour of cholesteryl esters in the core of LDL particles. He also investigated the thermal stability of HDL, particularly that of its major protein, apolipoprotein A-I. R. Biltonen (University of Virginia, Charlottesville), using differential scanning calorimetry, estimated the statistical distribution of cluster sizes in phospholipid bilayers, and H. Pownall (University of Texas, Houston) applied microcalorimetric techniques to examine the association between apolipoproteins and lipid vesicles. Fluorescence spectroscopy was used by A. Jonas (University of Illinois, Urbana) in a study of lipoproteins and apoprotein-phospholipid-cholesterol recombinants; she proposed a bilayer structural model conceptually similar to that derived from X-ray and thermocalorimetric data. Pownall described the kinetics and mechanisms of lipid-amphiphile association, whereas Smith discussed an interesting application of an extrinsic fluorescence probe (pyrene), to the study of cholesterol exchange between lipoproteins using stopped flow kinetics.

The current status of  $^{13}\text{C}$ -NMR spectroscopy as applied to studies of the structure of plasma lipoproteins was summarised by E. Cordes (Indiana University, Bloomington). The results presented indicated that this technique is valuable in the study of the dynamics and phase transitions of surface and core lipids, particularly in combination with the analysis of model systems. J. Morrisett (Houston) reported results of his  $^{13}\text{C}$  and  $^{31}\text{P}$ -NMR spectroscopic studies on lipoprotein-X, an abnormal lipoprotein found in cholestasis. T. Glonek (University of Chicago) discussed the use of a chelated manganese paramagnetic ion to probe the accessibility and surface distribution of the phospholipids in both LDL and HDL.

One session was devoted to an examination of the mechanism of phospholipase  $\text{A}_2$  action and its use as a probe of the lipoprotein surface. F. Kézdy and colleagues (Chicago) found that the kinetic behaviour of this enzyme is similar for all of the major lipoprotein classes investigated; he therefore suggested that all of the phospholipase  $\text{A}_2$ -hydrolysable phospholipids represent a single pool at the surface of these particles. M. Wells (University of Arizona, Tucson) presented evidence that the physical state of the substrate influences the specificity of phospholipase  $\text{A}_2$  and pointed at the limited information available at present on the mechanism of action of

## Red hot sea

from Peter J. Smith

It is as certain as anything can ever be in the Earth sciences that the Red Sea is a region of very young seafloor spreading. Some of the evidence for this view comes from geothermal studies, which is only to be expected, although it comes as a surprise to be reminded by Girdler and Evans (*Geophys. J.* **51**, 245; 1977) that as recently as 1970 there were no more than 17 heat flow values available, 5 of which were only estimates from borehole temperature measurements. Since 1970, however, the quantity of data has increased fivefold, and Girdler and Evans have now been able to draw a much better, though still far from complete, picture of Red Sea geothermal characteristics.

The average heat flow for measurements made within 5 km of the Red Sea's deep water axis is  $467 \text{ mW m}^{-2}$ , or about eight times the world average of  $59 \text{ mW m}^{-2}$ , although individual values rise to more than 56 times the world average. Over the next 5-km interval the average then drops dramatically to  $89 \text{ mW m}^{-2}$ , presumably because of hydrothermal circulation; but it rises to  $140 \text{ mW m}^{-2}$  and  $165 \text{ mW m}^{-2}$  over succeeding 20 km intervals, settling to about  $111 \text{ mW m}^{-2}$  (still about twice the world mean) at distances of 50–170 km.

Thus heat flow is high not only in the axial zone but throughout the whole of the Red Sea. Indeed, both heat flow and temperatures ( $100^\circ\text{C}$  at

depths of less than 2 km) are so high along the edges of the sea that Girdler and Evans see geothermal heat as a potential source of power for coastal towns. But only 7 of the 86 individual heat flow values published by the end of 1975 lie below the world average; and as all come from the vicinity of the deep axial trough where heat flow is typically high, they would seem to reflect only transient thermal effects such as sediment slumping, or perhaps their positions above the downgoing limbs of hydrothermal circuits.

Sedimentary movement and hydrothermal circulation in the axial zone probably also explain the high variability of heat flow near the centre of the Red Sea. According to Girdler and Styles (*Nature*, **247**, 7; 1974) there have been at least two phases of seafloor spreading, the lithosphere produced by the second intruding and heating the older lithosphere and overlying evaporites; and although some people would dispute this precise interpretation, there seems every reason to suppose that evaporite movement has resulted from very recent spreading. Such complexity makes detailed interpretation of heat flow data difficult; but the general geothermal picture is evidently entirely consistent with the Red Sea as a young spreading zone. □

Peter J. Smith is a Reader in the Department of Earth Sciences at the Open University.

the enzyme. L. Smith (Houston) discussed the mode of activation of a purified milk lipoprotein lipase preparation by fragments of apolipoprotein C-II, the specific activator of the enzyme, and identified regions considered to be specific for activation. He discussed a similar approach with lecithin-cholesterol acyl transferase, in which he used fragments of apolipoprotein C-I, one of the activators of the enzyme.

With regard to apolipoproteins, W. Fitch (University of Wisconsin, Madison) presented an elaborate study on structural predictions based on primary sequence data. The findings led to the recognition of striking internal homologies in apolipoprotein A-I, considered to originate from duplication and crossing over of an ancestral gene coding for an 11-residue repeat. A computer search for amphipathic helices in apolipoprotein was discussed by J. Segrest (University of Alabama, Birmingham), whose results support the hypothesis that these segments might

be responsible for lipid binding. G. Fasman (Brandeis University, Waltham) provided a lucid analysis of the role of  $\beta$ -turns in protein structure and of the experimental methods used for their detection. The importance of  $\beta$ -turns in apolipoprotein structure emerged from work by investigators at the University of Chicago, who presented the first full-scale space-filling model of human HDL $_3$ , based on available experimental data and on work in progress on the properties of the A apolipoproteins at the air-water interface. One major conclusion from these investigations was that all of the predicted structures ( $\alpha$ -helix, random coil, and  $\beta$ -turns) in apolipoprotein A-I and A-II are amphipathic, and that this unique property enables them to occupy predictable areas at the HDL surface. □

## X-ray burst sources

Walter H. G. Lewin & Paul C. Joss\*

*More than 30 X-ray burst sources have been discovered in the past 2 years, and information on the observational properties of the burst emission is accumulating rapidly. The physical mechanism responsible for the bursts is so far undetermined, but the most promising models are based on the accretion of matter onto a compact object of Stellar mass.*

X-RAY bursts from a source in the globular cluster NGC6624 were discovered by Grindlay and Heise<sup>1</sup> in December 1975. Earlier, events had been reported that were believed to be hard X-ray bursts of cosmic origin<sup>2</sup>. However, after lengthy discussions between one of us (W.H.G.L.) and Dr Melioranski, we believe that these bursts and others reported by the same group<sup>3,4</sup> are not of cosmic origin but are probably caused by the Earth's magnetosphere.

In 1976 a further 19 X-ray burst sources were discovered, mostly by SAS-3 and OSO-8 (refs 5–7). To date (15 September 1977) the total number of burst sources is in excess of 30; they are strung along the galactic equator (Fig. 1) and the majority of them are located within  $\sim 35^\circ$  of the galactic centre<sup>7</sup>. At least two (but probably several more) are located in globular clusters<sup>8–12</sup>, and three burst sources have been tentatively identified with faint blue stars<sup>13–15</sup>. One of these identifications, proposed by McClintock, is almost certainly correct<sup>13,16</sup>.

A typical burst rises in less than a few seconds and lasts several seconds to minutes. In most bursts, the lower energy flux persists longer than the higher energy flux (Fig. 2). In at least three cases<sup>17–19</sup>, the time-dependent burst spectra can be fitted well by blackbody emission from a source with an effective radius of  $\sim 10$  km. If this interpretation is correct, there is good reason to believe that the burst sources are neutron stars or black holes of stellar mass.

The bursts are sometimes emitted at approximately regular intervals of from hours to days. At least eight burst sources emit a persistent (though variable) flux of X rays. No persistent emission has been detected from at least two burst sources<sup>5,20,21</sup>.

The mechanism which produces X-ray bursts is not yet known. There is little evidence to suggest that the burst sources are in binary systems, though many workers favour this idea. No proposed model has yet given a complete explanation for the behaviour of burst sources.

### Galactic distribution

If we adopt as an operational definition for X-ray bursts<sup>5</sup>: (1) rise time less than a few seconds, (2) duration from a few seconds to a few minutes, and (3) recurrence, then eighteen burst sources have been reported to date<sup>7,12</sup> (15 September 1977). Their positions are shown in Fig. 1. If we accept single burst-like events for which only the first two criteria were met, seven burst sources can be added (dashed lines and horizontal bars in Fig. 1). At least five more burst sources (not shown in Fig. 1) have been observed with SAS-3; their positions are very uncertain but they are probably all located within  $\sim 30^\circ$  of the galactic centre.

Many other burst-like events of cosmic origin that we omit have been reported in the literature; they are not known to meet either the rise time or the recurrence criterion. In this context we mention the intriguing results of the Los Alamos group<sup>22–24</sup>. It is very likely that some of the many events observed by them were X-ray bursts of the kind discussed here.

The burst sources are spread along the galactic equator and cluster near low galactic longitudes ( $|l| < 35^\circ$ ). The distribution is different from that of the known X-ray sources with 'steady' emission<sup>5,7</sup>. Eight burst sources (Table 1) have been identified with sources of steady emission (more will undoubtedly follow). This suggests that the burst sources form a subset of the steady X-ray emitters<sup>5,7</sup>. No steady emission has been observed from at least two sources<sup>5</sup>.

### Burst flux and recurrence

The observed peak intensities in bursts are typically  $\sim 10^{-8}$  to  $\sim 10^{-7}$  erg cm<sup>-2</sup> s<sup>-1</sup>. At source distances of  $\sim 10$  kpc, this would imply a peak luminosity of  $\sim 10^{38}$ – $10^{39}$  erg s<sup>-1</sup>.

The total (integrated) flux of individual bursts differs by about 1–2 orders of magnitude from source to source. In general, the total flux of individual bursts from a given source does not change appreciably over a time scale of many burst intervals<sup>5,6</sup>.

Aside from the short rise times (less than a few seconds) and the longer decay times (several seconds to minutes), an important characteristic of X-ray bursts is their recurrence (not reported for  $\gamma$ -ray bursts). As first reported by Clark and his associates<sup>25</sup>, the recurrence is sometimes regular though not strictly periodic. The most regular burst intervals have been observed from MXB1659–29. During October 1976 the burst intervals from this source wandered slowly from 2.0 to 2.6 h, and the burst arrival times were often predictable to within several minutes<sup>5,20</sup>. Again, during the recent worldwide coordinated burst observations<sup>26</sup> in June and July 1977, SAS-3 detected a series of 17 bursts (intervals  $\sim 2.5$  h) with arrival times often (but not always) predictable to within 5 min. It may not be a coincidence that MXB 1659–29, which is the most 'regular' of all burst sources, does not emit a detectable flux of 'steady' X-rays<sup>5,20</sup>.

The apparent regularities in burst occurrence for several sources can persist for days<sup>5,6</sup>. During recent SAS-3 observations, however, we found that many sources that were believed to be regular actually become irregular on time scales of days to weeks. The most striking examples of highly irregular burst sources are MXB1837+05 (refs 27–29) and MXB1735–44 (ref. 30 and unpublished SAS-3 results); their burst intervals can vary from  $\sim 1$  h to  $\sim 2$  d.

The fact that most known burst sources have intervals from hours to days is probably the result of a selection effect due to the limitations of today's X-ray observatories; the longer the

**Fig. 1** Sky map (galactic coordinates) of 18 X-ray burst sources which meet the three burst criteria (see text). Seven additional sources are shown for which the recurrence criterion of the bursts has not (yet?) been met. They are indicated with dashed lines (four sources) or with horizontal bars (three sources). Open error regions have areas  $\geq 3 \text{ deg}^2$ . The dashed line near the galactic anticentre represents an error box of  $\sim 120^\circ \times 2^\circ$ . The figure contains only burst sources reported before 15 September 1977. There are at least five additional known sources with poorly determined positions (see text). The names of some of the best studied burst sources are shown.

burst intervals, the smaller the chance of detection. It is likely that sources will be discovered with considerably longer burst intervals (weeks, months, years?). There are at present seven sources (Fig. 1) from which only one burst has been observed, yet some of these sources were observed continuously for many days. This may already be an indication that some of them have burst intervals in excess of several days. It is expected that in the era of the space shuttle, sensitive X-ray detectors will be flown with both large fields of view and the capability of determining source positions accurately. Such instruments would be ideal for the study of fast transient phenomena such as bursts.

It is thought that most burst sources have burst-active and inactive periods<sup>5,6</sup>. The most striking examples are MXB1820-30 (in NGC6624), MXB1730-335 (the rapid burster), MXB1743-28, and a burst source in Norma (refs. 5, 6, 21, 30-36). There is no indication that the periods of activity come at regular intervals, but this may well be the case for some sources. A possible (so far undetected) periodicity in the burst patterns or in the active and inactive periods could, in principle, uncover an orbital period of a binary system.

## Burst profiles

Bursts exhibit a large variety of shapes. There are bursts with spikes, peaks, bumps, shoulders and tails, and some show all these features<sup>5</sup>. Bursts from different sources usually look very different (Fig. 2). Bursts from one source, however, usually seem quite similar. Several burst sources have their own characteristic idiosyncracies, and we can often (but not always) tell by the burst profile from which source a burst came (Fig. 2). All eight bursts detected from MXB1743-29 (at  $\sim 35$ -h intervals) showed two (sometimes three) distinct peaks at energies above 6 keV (ref. 33). Bursts from MXB1735-44 are usually narrow, lasting only 4-6 s<sup>30</sup>. Bursts from MXB1636-53 and MXB1728-34 have fast initial decays (a few seconds) followed by long gradual decays at low energies<sup>18,19,37</sup>. There are cases, however where the bursts from one source look very different. Bursts from MXB1837+05 show great variation<sup>29</sup> which may be related to the irregularities in the burst intervals. Normally, bursts from MXB1728-34 occur quite regularly with intervals that wander slowly from  $\sim 4$  to  $\sim 8$  h<sup>18,37</sup>. But, in June 1977, during the worldwide coordinated burst observations<sup>28</sup>, only one burst was observed in 54 h, and the profile of this burst was very peculiar. During observations in July 1977 the bursts from MXB1728-34 again occurred regularly and seemed 'normal'. There is some observational evidence that

bursts which occur 'out of sequence' in a quasi-regular series have a different appearance from the other bursts in the series. This effect has been reported in bursts from MXB1636-53, MXB1916-05 and MXB1730-335 (the rapid burster) (refs. 19, 21, 38 and unpublished SAS-3 results).

Clark *et al.*<sup>31</sup> have observed 22 bursts from MXB1820-30 (in NGC6624). The burst intervals slowly wandered from  $\sim 3.4$  h to  $\sim 2.2$  h. The burst tails, which were clearly visible at the beginning of the observations, vanished gradually and were absent from the last few bursts. The burst activity came to a halt while the persistent emission from the source continued to increase.

## Burst spectra

Significant spectral changes occur during bursts. Typically the spectra soften considerably during burst decay (Fig. 2 and refs. 5, 6). The best examples are the bursts from MXB1743-29 (ref. 33), MXB1906+00 (ref. 39), MXB1735-44 (ref. 30 and unpublished SAS-3 results), MXB1728-34 (refs 18 and 37), MXB1636-53 (refs 19 and 40), MXB1916-05 (refs 41-43), MXB0512-40 (in NGC1851, ref. 10 and G. W. Clark, personal communication) and a source near  $l^{\text{II}} \sim 356^\circ.4$ ,  $b^{\text{II}} \sim 2^\circ.3$  (ref. 17). Spectral hardening during burst decay has only been observed in bursts from MXB1820-30 (refs 8, 25). Spectral hardening during the burst rise is quite common, however, and has been observed in bursts from MXB1728-34, MXB1636-53, MXB1820-30, MXB0512-40 and in a single burst from a source near  $l^{\text{II}} \sim 356^\circ.4$ ,  $b^{\text{II}} \sim 2^\circ.3$ . MXB1837+05 is special, as some bursts harden during the rise and others soften<sup>29</sup>.

Swank *et al.*<sup>17</sup> and Hoffman *et al.*<sup>18,19</sup> have found good blackbody fits to the spectra of bursts from three burst sources (MXB1728-34, MXB1636-53 and a source near  $l^{\text{II}} \sim 356^\circ.4$ ,  $b^{\text{II}} \sim 2^\circ.3$ ). During the early part of the bursts, the temperature increases to  $\sim 3 \times 10^7$  K. A cooling is then observed which continues for several minutes, after which there is no longer any detectable flux. If indeed the burst emission is blackbody radiation, the effective radius  $R$  of the emitting region can be calculated. Swank *et al.*<sup>17</sup> find that  $R \sim 100d$  km during the first 20 s of the burst and  $R \sim 15d$  km for the remainder of the burst, where  $d$  is the source distance in units of 10 kpc. Hoffman *et al.*<sup>18,19</sup> find for both MXB1728-34 and MXB1636-53 that  $R \sim 10d$  km. This size remains approximately constant throughout the bursts. These results suggest that, if the source distances are  $\sim 10$  kpc, then the bursts are produced by a neutron star or a black hole of stellar mass<sup>17-19</sup>.

Hoffman *et al.*<sup>19</sup> have discussed 'typical' bursts in terms of

two components: (1) an initial pulse which rises and falls sharply in a few seconds and is wider at higher energies, followed by (2) a long decay whose spectrum softens with time as the burst intensity gradually decreases (Fig. 2). They made the interesting observation that the initial pulse appears to be highly absorbed at low energies (1–3 keV) when a burst in a quasi-regular series arrives out of sequence (too early) (ref. 19 and unpublished SAS-3 results).

### Steady emission

It is quite common for a burst source to emit a persistent (but variable) flux of X-rays<sup>5,8</sup>. As shown in Table 1, high 'steady' fluxes ( $\sim 1/4$  that of the Crab Nebula) are observed from MXB1636–53 (refs 40, 44, 45), MXB1728–34 (refs 18 and 37), MXB1735–44 (ref. 30) and MXB1837+05 (refs 27–29). No steady flux has been observed from either MXB1730–335 (ref. 31) or MXB1659–29 (ref. 5).

Table 1 lists eight burst sources and the accurate SAS-3 positions of their associated steady sources (refs 46 and 47 and J. G. Jernigan, personal communication). It is highly probable that all associations in Table 1 are correct; the probability (based on the positional coincidences) that any one of them is wrong is  $\sim 1\%$ . It has been suggested<sup>33</sup> that the three burst sources near the galactic centre produce a steady emission that may account for part of the emission of GCX (ref. 54). There are a few more burst sources for which a candidate steady source has been proposed<sup>12, 34, 48, 53</sup>.

The ratio of time-averaged luminosity of the steady emission to that of the burst emission varies from  $\lesssim 2$  (rapid burster) to  $\sim 250$  (ref. 19). If we exclude the rapid burster, the lowest value is  $< 25$  for MXB1659–29 (unpublished SAS-3 results). These ratios are important in testing nuclear-flash models of X-ray bursts (see section on theoretical models).

### Optical identifications

There are optical candidates<sup>13–18</sup> for three burst sources (MXB1837+05, MXB1636–53 and MXB1735–44). All three are faint ( $\sim 18$  mag) blue stars. At least one star, recently suggested by McClintock, is almost certainly a correct identification<sup>13, 18</sup>.

Very accurate positions for the steady sources that produce bursts have recently been reported by the Ariel 5 group in Birmingham<sup>61</sup> and the SAS-3 group<sup>46, 47</sup>. It is expected that as a result more optical identifications will soon follow.

The burst sources MXB1820–30 and MXB0512–40 are located in the globular clusters NGC6624 (refs 8, 25, 31) and NGC1851 (refs 10 and 11), respectively. The rapid burster<sup>21</sup> (MXB1730–335) is almost certainly located in 'Liller's' globular cluster (refs 5, 6, 9, 55), and a burst source with a positional accuracy of  $\sim 1^\circ$  may be located in the globular cluster NGC6441 (ref. 12). Thus, a very high fraction of the seven known X-ray emitting globular clusters<sup>56</sup> also emit bursts, and it is expected that more burst sources will be found in globular clusters. The large majority of burst sources, however, (Fig. 1) are not located in visible globular clusters<sup>5–7</sup>.

### Spectra and character of associated steady sources

The spectra of the persistent X-ray emission of burst sources do not fit a blackbody model and are almost always softer than the mean burst-spectra<sup>5</sup> (integrated over the first  $\sim 10$  s of the burst). The only exception is 4U1915–05 (MXB1916–05), for which a hard spectrum ( $kT > 35$  keV) has been reported for the steady emission<sup>43</sup>.

At Ostriker's suggestion<sup>57</sup>, Cominsky (personal communication) has compared 'colour-colour' plots of the steady X-ray emission from eight burst sources (the hard source 4U1915–05 was not included) with that of other types of X-ray source (five globular clusters, seven strong galactic centre sources, one pulsating low-mass binary, two non-pulsating low-mass binaries, seven high-mass binaries, and two black hole candidates). She concludes that the colour-colour plots are similar for: (1) the burst sources (steady emission), (2) the globular cluster X-ray sources, (3) the strong galactic centre sources, and (4) the non-pulsating low-mass binaries (Sco X-1 and Cyg X-2). The colour-colour plots, however, are different for the high-mass binaries, the pulsating low-mass binary (Her X-1) and the two black hole candidates (Cyg X-1 and Cir X-1). This suggests that the first four categories may have very similar mechanisms for producing X-rays and that they may well all be binaries. But, if the burst sources are binaries, one may wonder why none of them shows any evidence of their binary character. On the other hand, it is very difficult to deduce a possible binary membership from X-ray data if no pulsations or eclipses are observed (as in Sco X-1 and Cyg X-2) and if the approximate binary period is not already known (for example, from optical observations). It may well be that the possible binary character of X-ray burst sources will first be found in optical data. It is expected that the optical

candidates<sup>13-16</sup> will be carefully examined for evidence of binary characteristics.

### The rapid burster

The rapid burster (MXB1730-335) is quite unlike all other burst sources<sup>21</sup>. It can produce up to 4,000 bursts per day<sup>6</sup>, the integrated energy  $E$  of individual bursts can vary by two orders of magnitude, and  $E$  is approximately proportional to the time  $\Delta t$  for the next burst to occur<sup>21</sup>. A more detailed analysis has shown that the linear relation breaks down at low burst energies, where the waiting time to the following burst is considerably longer than one would expect from a strictly linear relation<sup>6</sup>.

Occasionally, 'anomalous' bursts have been observed that occur more or less independently of the rapidly repetitive ('normal') burst sequence, grossly violating the  $E-\Delta t$  relation<sup>38</sup>. These 'anomalous' bursts in general rise more slowly, and their maximum luminosity is  $\sim 1/3$  that of the maximum observed luminosity in 'normal' bursts<sup>38</sup>.

The rapid burster is almost certainly located in a globular cluster<sup>9,55</sup>, whose position is inside the small error circle (1.8 arc min radius) for the burst source<sup>6,51,58</sup>. As noted above, no steady emission has been observed from this source; the ratio of time averaged steady flux to time averaged burst flux is  $\lesssim 2$  (ref. 21), which is uniquely low<sup>5,6</sup>. This source was burst-active in March-April 1976, in April-May 1977 and in September 1977 (refs 21, 30, 35, 36, 59). Bursts from this source have also been detected with Uhuru<sup>48</sup>.

The time averaged burst luminosity varied significantly (by factors of  $\sim 2-3$ ) during March and April 1977<sup>5</sup>. The latest SAS-3 results, obtained by H. Marshall (personal communication) show a hint of a period of about 0.8 d in the time averaged burst luminosity.

### Comparison with $\gamma$ -ray bursts

The most striking differences between X-ray bursts and  $\gamma$ -ray bursts<sup>60</sup> are: (1) X-ray burst sources cluster along the galactic equator whereas  $\gamma$ -ray burst sources do not; (2) unlike  $\gamma$ -ray bursts, X-ray bursts are repetitive on time scales of hours to

days; (3) the spectra of  $\gamma$ -ray bursts are much harder than those of X-ray bursts; and (4) the total flux density of a  $\gamma$ -ray burst is typically  $\sim 2$  orders of magnitude higher than that of an X-ray burst. The  $\gamma$ -ray bursts cannot be the high-energy tails of normal X-ray bursts produced by nearby burst sources; the absence of recurrence excludes this possibility. However, some generic relation between  $\gamma$ -ray bursts and X-ray bursts cannot be excluded<sup>34</sup>. It is interesting to note that a  $\gamma$ -ray burst (from galactic latitude  $\sim -46^\circ$ ) observed from Apollo 16 shows a triple-peaked time structure<sup>61</sup>, which is remarkably similar to the structure in bursts from MXB1743-29 (Fig. 2 and ref. 33).

### Theoretical models

Most speculations concerning the nature of X-ray burst sources fall into two broad categories: (1) instabilities in the accretion of matter onto a compact object (white dwarf, neutron star, or black hole), and (2) thermonuclear flashes in matter accreted onto the surface of a neutron star. Theoretical models based on these ideas are still rather primitive.

Among possible instabilities in accretion onto a compact object of roughly solar mass, most models are based on interchange instabilities at the Alfvén surface of a neutron star or white dwarf. Within this category, Lamb *et al.*<sup>62</sup> have investigated the possibility of a thermal instability in spherical accretion onto a magnetised neutron star, while Svestka<sup>63</sup>, Henriksen<sup>64</sup>, Baan<sup>65</sup> and Joss and Rappaport<sup>66</sup> have discussed the possible role of orbital motion of the accreting matter in producing an instability. Wheeler<sup>67</sup> and Liang<sup>79</sup> have investigated instabilities within an accretion disk surrounding a compact object. These preliminary discussions are a promising start. The physics of the proposed instability mechanisms is very complex, however, and no completely satisfactory model has yet been established.

Grindlay and Gursky<sup>68</sup> and Grindlay<sup>69</sup> have presented the idea that the burst sources may be associated with massive ( $\gtrsim 10^3 M_\odot$ ) black holes. A specific mechanism for producing the burst emission was suggested by Bahcall and Ostriker<sup>70</sup>, who invoked a compact object in orbit about a massive black hole,

which interacts with an accretion disk that surrounds the hole. The latter idea is by now excluded; we now know that the burst intervals are often very irregular, unlike the highly periodic behaviour that one would expect from this model.

The introduction of massive black holes was largely motivated by the association of 3U1820-30, the earliest discovered burst source, with the globular cluster NGC6624 (ref. 8). This cluster is one of five globular clusters which have highly condensed cores and which contain sources of persistent X-ray emission<sup>66</sup>. It had previously been suggested<sup>71,72</sup> that these steady X-ray sources may be massive black holes undergoing accretion within the cluster cores. However, as more burst sources were discovered, it was found that the distribution of these sources is very different from the apparently spherical distribution of globular clusters about the galactic centre (Fig. 1 and refs 5-7). This fact, together with the absence of visible globular clusters in the direction of many burst sources, now makes it almost certain that the majority of burst sources are not located in globular clusters.

Another motivation for the massive black hole model was the spectral hardening observed during the decay in bursts from NGC6624 (refs 8, 25), which was ascribed to Compton scattering of the emitted X rays by a very hot ( $\sim 10^9$  K) gas cloud that is gravitationally bound by a massive black hole<sup>68</sup>. Canizares<sup>73</sup> has shown, however, that the observed hardening could be produced by scattering in a cooler cloud, which might be bound by a compact object of mass  $\lesssim 5M_\odot$ . Moreover, bursts from most other sources, including the one located in the globular cluster NGC1851, soften during their decay (Fig. 2, refs 5, 6 and G. W. Clark, personal communication). As pointed out earlier<sup>5,6</sup>, it seems that little evidence is left to support the conjecture that X-ray bursts are associated with massive black holes.

Maraschi and Cavaliere<sup>74</sup> and Woosley and Taam<sup>75</sup> have suggested thermonuclear flashes in the surface layers of accreting neutron stars as a totally different alternative mechanism for the production of X-ray bursts. The gravitational energy released per unit mass of matter falling onto a neutron star of mass  $M$  and radius  $R$  will be  $(GM/R) \sim 10^{-1} c^2$ , while that released by very rapid (timescale  $< 10$  s) thermonuclear fusion of any nuclear fuel will be  $\lesssim 10^{-3} c^2$  (refs 76, 77). Hence, this type of model predicts that the ratio,  $\alpha$ , of time averaged persistent accretion-driven X-ray luminosity to time averaged burst luminosity should exceed  $\sim 10^3$ . This criterion is apparently met by some burst sources with rather bright steady X-ray counterparts (Table 1 and refs 5, 6). However, it apparently fails in the case of the rapid burster, for which  $\alpha \lesssim 2$  during times of burst activity<sup>21</sup>. It also seems to fail for MXB1659-29, whose observational properties are similar to those of most other burst sources (unlike the rapid burster) but which has recently been found to have  $\alpha < 25$  during burst-active times (unpublished SAS-3 results). Thus, it seems that this mechanism can account for no more than a subset of the presently known burst sources. In any event, a complete evaluation of the physics of thermonuclear flashes in neutron-star surface layers has yet to be carried out.

If the burst sources, are in fact, compact objects of moderate mass, then they may be accreting matter from close binary stellar companions. In this respect, they may be very similar to other binary X-ray sources, which are also widely believed to consist of compact objects that are undergoing accretion from relatively normal companion stars (see ref. 78 and references therein). If the burst sources are in such systems, one might expect to find periodic temporal variability in the associated steady X-ray emission or in the optical candidates. As noted above, however, no such periodic variability has been reported to date.

The blackbody spectra reported for three burst sources (see section on burst spectra and refs 17-19) are the only direct indication to date that burst sources are neutron stars or black holes of stellar mass.

The mechanism which produces X-ray bursts is thus not yet known, but the most promising mechanisms are based on the

accretion of matter onto a compact object of Stellar mass.

We thank Jeffrey Hoffman and Lynn Cominsky for useful comments. This work was supported in part by the US NASA. P.C.J. is an Alfred P. Sloan Research Fellow.

**Note added in proof:** Recently, Hoffman, Marshall and Lewin<sup>80</sup> discovered that the rapid burster occasionally produces 'special' bursts which, unlike the rapidly repetitive bursts, show the typical characteristics of bursts from other sources (similar time scale of burst intervals and similar spectral evolution during burst decay). They suggest in a recent preprint that rapidly repetitive bursts may be a replacement of the persistent emission observed from many other burst sources and that in this special case the persistent emission manifests itself as bursts. If this were so, it opens the interesting possibility that the rapidly repetitive bursts may be the result of instabilities in the accretion flow (gravitational potential energy) but that the 'special' bursts from the rapid burster and the X-ray bursts from all other sources are the result of thermonuclear flashes.

# Oxygen isotope and palaeomagnetic evidence for early Northern Hemisphere glaciation

N. J. Shackleton

N. D. Opdyke

Lamont-Doherty Geological Observatory, Columbia University, Palisades, New York 10964.

*Oxygen isotope and palaeomagnetic analysis of the lower half of LDGO piston core V28-179 shows that glacial-interglacial fluctuations have characterised Earth's climate for the past 3.2 Myr, before which there was a period of stable 'interglacial' or 'preglacial' climate. The scale of glaciations increased about 2.5 Myr ago.*

THE stratigraphically longest detailed oxygen isotopic records from the oceans extend to sediments about 2.1 Myr old<sup>1,2</sup> and indicate Pleistocene-like glacial events well below the horizon stratigraphically equivalent to the base of the Quaternary as it is defined in Italy<sup>3</sup>. Here we extend the isotopic record and identify the onset of these quasi-cyclic glacial-interglacial fluctuations. For this we required a core of sediment that accumulated somewhat more slowly than in the area of our previous studies.

Cores from the Equatorial Pacific were described by Hays *et al.*<sup>4</sup>, who showed that north of the belt of maximum biological productivity along the equator it is possible to take piston cores containing a record extending well into the Pliocene. They discussed the lithostratigraphy and magnetostratigraphy of several cores, and the biostratigraphic record for foraminifera, diatoms and radiolaria (expanded in refs 6 and 7) while Gartner<sup>5</sup> presented the nannofossil stratigraphy. Since then several cruises have recovered cores from the same general area. Of these we selected V28-179 (collected by N.D.O.), for isotope analysis because it contained the thickest accumulation of sediment for the Gauss magnetic epoch.

Core V28-179 was taken at 4° 37' N, 139° 36' W in 4,509 m water depth. The core comprises alternating layers of foraminiferal chalk ooze, marl ooze and marl with some dominantly diatomaceous layers. Most of the core is intensely burrowed, and many of the plugs of sediment washed for analysis could be seen to contain components of slightly different colour mixed

Fig. 1. Magnetic record for core V28-179, 150 Oe and interpretation in terms of the standard palaeomagnetic polarity scale.

Table 1 Magnetic boundaries V28-179

Brunhes-Matuyama	527±2.5 cm
Matuyama-Jaramillo	657±4 cm

Kaena-Gauss	1,517±2.5 cm
Gauss-Mammoth	1,558±2 cm
Mammoth-Gauss	1,622±2.5 cm
Gauss-Gilbert	1,779±2.5 cm
Unnamed short interval (1,808-1,817±2.5 cm)	

together by burrowing. This strongly suggested that the depth through which burrowing took place was frequently greater than the typical thickness of a single layer deposited under uniform environmental conditions. We assume, following evidence already available<sup>9</sup>, that the chief source of variability in the sediment derives from climatically controlled variations in the proportion of carbonate remaining in the sediment. As these variations occurred on a depth scale that was smaller than the depth of plainly imperfect homogenisation by burrowing organisms, it shows that we are limited to an investigation of the general character of the ocean oxygen isotopic record within the good time-framework provided by the palaeomagnetic record of the core.

The record of changing ocean oxygen isotopic composition in the Late Pleistocene has been investigated in some detail in cores with accumulation rates up to about 8 cm kyr<sup>-1</sup> (ref. 10), and it has been shown that some cores with accumulation rates of over 3 cm kyr<sup>-1</sup> preserve a sufficiently good record to allow the identification of the effect of the changing tilt of the Earth's orbit (period 40 kyr) and of precession of the equinoxes (period about 23 kyr)<sup>11</sup>. To investigate the Lower Pleistocene in a piston core, it is necessary to work in an area of rather lower sediment accumulation. We have already discussed<sup>1</sup> the loss of information which characteristically occurs under these conditions. Even if the mixing in the sediment of core V28-179 were homogeneous, climatic fluctuations with a 40 kyr period would have a wavelength in the sediment of only about 20 cm and would be scarcely detectable. Since the mixing is clearly not homogeneous, and since several samples proved too low in carbonate for an analysis to be made at all, it is likely that the detailed character of the climatic record is inaccessible. What we can do is to identify the date of inception of the isotopic fluctuations which have characterised at least the whole of the Pleistocene<sup>1</sup>. Although there are other types of evidence which indicate periods of climatic deterioration, there is as yet no information pertaining to the date of the earliest accumulation in the Northern Hemisphere of continental ice sheets that would have been of sufficient scale to produce a detectable effect on the oxygen isotopic composition of the oceans<sup>12</sup>.

The core was sampled for magnetic measurement at 5 cm intervals along its length. The measurements were performed on a slow speed fluxgate magnetometer of the type described by Molyneux<sup>13</sup>. In order to ascertain the proper alternating field to use for blanket demagnetisation and to determine the magnetic stability of the core 10 samples spaced throughout the core were progressively demagnetised in peak alternating fields of up to 250 Oe. The magnetic stability was found to vary throughout the length of the core with values of the median destructive field ranging from 25 to 225 Oe. Natural remanent magnetic intensities ranged from 0.2 to 20 × 10<sup>-6</sup> e.m.u. cm<sup>-3</sup>. A field of 150 Oe peak value was selected for blanket demagnetisation. The resulting plot of declination change against depth is shown in Fig. 1 plotted relative to an arbitrary fiducial mark scribed on the ship during the extrusion process<sup>14</sup>. The correlation of the resulting magnetic pattern to the standard time scale is easily done since the reversals are clearly delineated. This correlation has been confirmed by foraminiferal studies<sup>15</sup>

using the foraminiferal zonation previously determined for equatorial Pacific sediments<sup>4,6,7</sup>.

An important fact is that the pattern of coiling changes in *Pulleniatina* and in *Globorotalia tumida* shows that the lowest reversely magnetised section of sediment below about 18m can only represent the interval from the Gilbert-Gauss boundary to a horizon somewhat later than the Cochiti event; the bottom of the core probably has an age between 3.5 and 3.6 Myr (ref. 15).

Fig. 2 Oxygen isotopic composition of *Globocassidulina subglobosa* in core V28-179 from 10m to 21m. *G. subglobosa* living on the sea floor at the coring site today would have an  $^{18}\text{O}$  content of about +3.50‰. Magnetic events are indicated by O (Olduvai), K (Kaena) and M (Mammoth). Ages indicated are based on current estimates of the chronology for the magnetic record<sup>26</sup>.

The placement within the core of the major palaeomagnetic transitions are given in Table 1. The only departure of the magnetic stratigraphy from the standard magnetic time scale is the presence of a short normally magnetised interval at 1,800 cm, below the Gauss normal magnetic epoch. It is possible that this represents a short reversal of the magnetic field since the core does not show any apparent physical disturbance at this level.

Oxygen isotope analyses were made at 10 cm intervals in the samples previously used for magnetic studies. The samples were dispersed in distilled water in a mechanical shaker, and after brief ultrasonic treatment, they were sieved on a 125  $\mu\text{m}$  mesh and dried in a cool oven on the sieves. Foraminifera for isotopic analysis were taken from this fraction further cleaned ultrasonically and purified by roasting *in vacuo* at 400 °C for 30 min. Carbon dioxide was released from the carbonate by the action of 100% orthophosphoric acid at 50 °C and analysed in a VGMicromass 602C mass spectrometer; analyses are reported to the PDB standard on the basis of multiple analyses of circulating standard carbonates.

The preservation of foraminifera is very poor at the water depth at which core V28-179 was taken (4,509 m). It was, therefore, generally not possible to obtain for analysis *Globigerinoides sacculifer*, the species used in our previous studies<sup>1,8</sup>. Instead, we chose to analyse benthonic foraminifera, which are less susceptible to dissolution. As many species of benthonic foraminifera do not deposit their carbonate in isotopic equilibrium with the sea water they inhabit<sup>18</sup>, it would clearly be desirable to analyse a single species throughout. *Uvigerina*, known to deposit carbonate in isotopic equilibrium, is extremely rare, but in the majority of samples we were able to extract sufficient specimens of *Globocassidulina subglobosa* for analysis.

To calibrate *G. subglobosa* for possible departure from isotopic equilibrium, we analysed the top part of core V19-28 from which we obtained excellent isotopic data for *Uvigerina*<sup>10,17</sup>. Our measurements show that *G. subglobosa* may be even closer to isotopic equilibrium than *U. senticosus*, the species analysed in core V19-28. Comparisons of the oxygen isotopic composition of *G. subglobosa* and of *U. spinulosa* in Oligocene samples confirms the suitability of this species for oxygen isotope work<sup>18,19</sup>. The bottom temperature at the site of core V19-28 is about 1.8 °C; at the site of V28-179 it is about 1.1 °C. The mean  $^{18}\text{O}$  content of *Globocassidulina subglobosa* in the upper part of core V19-28 is +3.30‰ (five analyses); using the relationship  $T = 16.9 - 4.4\delta + 0.10\delta^2$  (refs 20, 21) enables us to estimate that the temperature difference between

the two sites should be equivalent to an isotopic difference of about 0.2 ‰, so that the expected value at the V28-179 site is about +3.50 ‰. Since the sediment accumulation rate at the coring site is only about 0.6 cm kyr<sup>-1</sup>, the core top would be likely to contain a mixture of glacial and recent specimens and would not be useful for calibration purposes.

Analytical results for *G. subglobosa* are given in Table 2, and are plotted in Fig. 2. The record may best be described as a caricature of the true course of events, in that it is certainly not possible to derive an accurate record of events in such gradually accumulating sediment. It is, however, quite clear that the uppermost 17 m of the core are predominantly glacial in character; below 17 m, isotopic values are consistently close to the present-day value. Taking this lower section first, we may conclude that between about 3.5 Myr and 3.2 Myr ago no big ice sheets accumulated in the Northern Hemisphere. Isotopically, the ocean was in an interglacial state, with more or less constant isotopic composition. The standard deviation among the measurements for this part of the core is 0.13 ‰. If this were entirely due to real variability, it would represent glacial events of a magnitude up to the equivalent of a 26 m range in eustatic sea-level fluctuation<sup>8</sup>. The variations are on so small a scale that if they derive from real glacial events, then they could be caused by changes in the Antarctic ice sheet, or by small Northern Hemisphere glaciations. It is conceivable, however, that this variability stems entirely from analytical error. More accurate measurements in a section with more rapid sediment accumulation will be needed to investigate possible small-scale glacial events earlier than 3.2 Myr ago.

Just below the Mammoth event at 1,680 m we see a positive excursion in isotopic composition that is well above possible analytical uncertainty and is of such a magnitude (0.4 ‰) as to represent about a 40 m sea-level equivalent in stored ice (assuming its isotopic composition was about -35 ‰). This date is in substantial agreement with the inception of ice-rafting observed in sediments from site 116 in Leg 12 of the Deep-Sea Drilling Project<sup>22</sup> and with evidence of glaciation in Iceland<sup>23</sup> and with ref. 12, but the present data give for the first time the scale of fluctuations which have continued ever since.

At the base of the Matuyama (sample at 1,310 cm) a glacial isotopic excursion of about 1.0 ‰ is observed. This is a characteristic extreme value over the lower Matuyama section. In deep-Pacific cores with a high accumulation rate the maximum difference between glacial and interglacial isotopic values in

the late Pleistocene is about 1.60 per mil (ref. 10). Thus we have clear evidence that glaciations of a magnitude of at least two-thirds that of the late Pleistocene glacial maxima were occurring in the time interval from 2.5 to 1.8 Myr ago. This was probably the scale of glaciation throughout the Lower Pleistocene<sup>1</sup>. Evidently a major change in the character of glaciations occurred at about 2.5 Myr ago. The substantial carbon isotopic event at that point in the record may represent a large drop in the continental biomass<sup>24</sup> and may have been associated with significant floral extinctions under severe environmental pressure<sup>25</sup>.

Few localities are likely to preserve a sea-level record for the past 3 Myr. But, it may be deduced from Fig. 2 that the last lengthy period of stable sea level and low ice volume terminated about 3.2 Myr ago, so that it is likely that a major constructional coral terrace feature is present in some areas dating from this time; marine highstands in the remaining Pliocene, like those of the Pleistocene, were probably brief. On the basis of this analysis one might advance the hypothesis that before 3.2 Myr ago, continental environments were relatively stable over a long period of time; since then the Earth has been subjected to the stress of continually fluctuating climate, with pleasant climates like our own occurring infrequently and lasting only about 10,000 years.

We thank NERC and NSF for financial support, M. A. Hall for his operation of the mass spectrometer, and W. A. Berggren and G. J. Kukla for helpful discussions.

## Immunological specificity and memory in a scleractinian coral

W. H. Hildemann, R. L. Raison, G. Cheung, C. J. Hull, L. Akaka & J. Okamoto

Immunogenetics Group, Department of Microbiology and Immunology and Dental Research Institute, University of California, Los Angeles, California 90024 and Department of Biology, Hilo College, University of Hawaii, Hilo, Hawaii 96720

*Tissue transplantation immunity with a specific memory component is demonstrated in populations of Montipora. This highly discriminating immunoreactivity derives from extensive allogeneic polymorphism of histocompatibility (H) markers. An H system of immunorecognition is postulated to have originated in multicellular invertebrates probably beginning with coelenterates.*

POSSESSION of a specific immune system, including immunorecognition leading to selectively inducible responses with a memory component, has long been considered unique to vertebrates. Although invertebrate defence reactions were thought to lack sharp specificity, we now know that metazoans ranging from coelenterates to protochordates possess a well-developed capacity for recognition of foreign tissue followed by antagonistic reactions. Among higher invertebrates, immunorecognition at the allogeneic level has been repeatedly described in annelid worms<sup>1,2</sup>, echinoderms<sup>3,4</sup>, and tunicates<sup>5,6</sup>. Convincing evidence of allogeneic incompatibility in coelenterates has been reported from controlled experiments with colonial hydroids<sup>7</sup>, gorgonians<sup>8</sup>, and anthozoans, including sea anemones<sup>9,10</sup> and corals<sup>11,12</sup>. The situation in sponges, the most primitive of multicellular animals, is less clear. Certain species exhibit allogeneic recognition yielding non-fusion of separate clones after an initial period of adhesion, but cytotoxic reactions have not been reported<sup>13</sup>.

Continuing scepticism concerning the existence of immunocompetence in invertebrates<sup>14,15</sup> focuses on ques-

tions of specificity, memory and the molecular basis of cytotoxic reactivity. A specific alloimmune memory component to transplantation immunity among higher invertebrates has already been documented in annelids<sup>16</sup> and in echinoderms<sup>4</sup>. In living corals, specific reactivity is demonstrated by consistent compatibility of intracolony or syngeneic transplants, while intercolony allografts and interspecific xenografts are invariably incompatible. These distinct reactions, characteristic of many scleractinian corals, are both naturally-occurring on tropical reefs and reproducible in laboratory experiments<sup>11,17</sup>. Quasi-immune surveillance in corals, with manifestations ranging from mild to severe, is evidenced by contact avoidance reactions, allogeneic contact incompatibility, chronic xenogeneic incompatibility and acute interspecific cytotoxicity. Positive recognition of foreignness in the form of non-fusion in areas of tissue contact precedes cytotoxic reactions which usually require a longer period of sensitisation. Examination of allogeneic graft reactions in *Montipora verrucosa*, a foliaceous reef-building coral abundant in the Hawaiian Islands, surprisingly suggested a specific immunorecognition system with a memory component of at least short-term duration<sup>12</sup>. We now present an extensively controlled study of the essential immunocompetence of this coelenterate as a function of polymorphism of histocompatibility (H) markers, specificity and memory.

### Experimental tissue grafts

*M. verrucosa* is most attractive for tissue grafting because of its flat configuration and rapid healing. Many techniques for placing pieces of coral in firm, soft-tissue contact have

Fig. 1 Intracolony isografts of *M. verrucosa* showing compatible fusion at interface (arrows) at 30 d after grafting. Technique of pair grafting on plexiglas base using monofilament nylon tie-downs is also illustrated. Approximately  $\times 1$ .

been tried. Notched plexiglas rectangles about  $23 \times 12 \times 1$  cm and high-test tie-downs of monofilament nylon proved adequate for grafting paired *Montipora* pieces ranging in dimensions from 9–72 cm<sup>2</sup> (Fig. 1). Heavy bone shears were used to cut pieces to desired size, but only uncut edges were joined as graft interfaces. Grafts were established by tying together laterally two pieces of living coral with 50 pound test monofilament nylon on plexiglas plates, using small lead crimps to bind the nylon firmly. All coral was maintained in a rapidly running and unfiltered seawater system at 24–26 °C; in these conditions at the University of Hawaii Facility at Leiliwi Bay, *Montipora* thrived for for many months. Coral pieces were kept immersed in seawater in large trays while grafting and scoring.

Tissue reactions at transplant interfaces were scored under a large platform stereomicroscope, usually at  $45\times$  magnification. Useful indicators of graft viability versus rejection were (1) allogeneic contact avoidance/inhibition evident by failure of soft tissues to fuse or grow across small gaps; (2) persistence or disappearance of pigmented zooxanthellae in coenenchyme at contact points; (3) hyperplasia/blanching/death of soft tissue in contact zones. Cytotoxic reactions of allogeneic incompatibility may be either unilateral or bilateral when first observed, but nearly all became bilateral in *Montipora*. For purposes of quantitating cytotoxic reaction times of allografts, zones of soft tissue death of 1 mm or more from either side of the interface were scored as definitive. This extent of tissue death is unequivocal when measured under the stereomicroscope (Fig. 2) and allowed different investigators to score the same grafts on successive days with objectivity. Initial allocytotoxic reactions of 0.5 mm or less may take 2–3 weeks to become definitive in occasional slow reactors.

Technical trauma sometimes causes slight tissue destruction ( $<0.5$  mm) that is evident within 24 h of establishing grafts, but which heals within 1 week after grafting. Unless otherwise stated, all isografts, first-set and repeat-set allo-

grafts in the present experiments were 12–16 cm<sup>2</sup> in area. Soft tissue to a depth of 1–2 mm overlies the hard calcareous skeleton. Other technical considerations have been described elsewhere<sup>12,17</sup>. Three widely separate populations of *M. verrucosa* from the island of Hawaii were used. Specific first- and second-set allografts involved comparison of Kapoho and Onekahakaha populations, and unrelated third-party allografts were from the City of Refuge reef. Time–percentage effect curves, reaction time ratios and slope function ratios were determined by nomographical methods<sup>18</sup>.

### Evidence of alloimmune specificity and memory

Control intracolony isografts were always compatible as shown by soft tissue fusion in all contact areas as early as 3–5 d after grafting. Neither blanching nor tissue hyperplasia accompanied this fusion in some 18 pairs tested. By 12–15 d, coenenchyme continuity with confluent zooxanthellae was observed throughout contact zones. Calcification was already well underway at interfaces, but gaps of 3 mm or more remained open. Smaller gaps disappeared as a result of bilateral outgrowth. By 24–30 d, complete reconstitution indistinguishable from normal ungrafted coral was evident (Fig. 1). This compatible fusion then persisted indefinitely.

Rejection of initial or first-set allografts was preceded by a lag or sensitisation period of 2–3 weeks during which time intimate soft tissue contact was established. Antagonistic reactions were then revealed by progressive blanching and loss of soft tissue in the immediate contact area. In a series of 32 test pairs, primary allografts yielded a median reaction time (MRT) of 22.0 (19.2–25.3) d. Secondary allografts, established by resetting the same coral pairs at new interfaces distant from the original contact area, showed accelerated and intensified cytotoxic reactions with an MRT of 11.6 (9.4–14.4) d. This MRT difference with an interval of 40 d between first-set and second-set grafting (Table 1)

Fig. 2 Intercolony allografts of *Montipora verrucosa* showing bilateral cytotoxic incompatibility restricted to immediate contact zone. Note blanching and soft tissue death at interface (arrows). Approximately  $\times 1$ .

Table 1 Evidence of specificity and memory in allograft reaction times of *Montipora verrucosa*

Allograft expt	No. coral pairs scored	Median reaction times (MRT) (d)*	Range of individual cytotoxic reaction times (d)	Interval between 1° and 2° grafting (d)§	Comment
First-set	32	22.0 (19.2–25.3) (9.2)	16–40	—	
Second-set	18	11.6 (9.4–14.4) (5.7)	9–23	40	MRT difference between 1° and 2° grafts highly significant†
Unrelated third-party Biphasic‡	21				
(1) Slow reactions	8	22.9 (18.4–28.5) (7.4)	23–35	41	MRT not significantly different from 1°; specific induced immunity not evident
(2) Rapid reactions	13	13.2 (9.7–18.0) (8.2)	8–17	41	MRT not significantly different from 2°; induced immunity is evident

\*Ranges in parentheses are 95% confidence limits; single numbers in parentheses below each entry are the standard deviations of the MRT's.

†Slopes of curves for first- and second-set reactions were parallel within experimental error, suggesting that same qualitative events occurred, but at different rates.

‡MRT difference between slow and fast reactors is significant at 95% confidence level. Note also that these two groups were qualitatively distinctive: slow reactions were concurrently bilateral, whereas rapid reactions were unidirectional as expected with one-way pre-immunisation.

§1°, First-set and 2°, second-set grafting.

was significantly suggestive of immune memory. Intensified second-set reactivity was evidenced by accentuated early hyperplasia and secretion of mucus at interfaces.

To test for specificity, 21 pairs of third-party grafts from a geographically distant City of Refuge population were performed with first-set rejectors from either Kapoho or Onekahakaha sources. These third-party grafts yielded a broad range of cytotoxic reaction times reflecting a biphasic distribution of accelerated and non-accelerated responses (Table 1). The rapid reactions (61%) were conspicuously unilateral, restricted to the third-party grafts as expected for unidirectional pre-immunisation. Conversely, the remaining slow reactions, not significantly different from first-set reactions, were concurrently bilateral and typical of primary reactions (Fig. 3). In other words, third-party grafts were distinguishable qualitatively on the basis of unilateral versus bilateral reactivity as well as quantitatively on the basis of cytotoxic reaction times. These striking results reveal both specificity in transplantation alloimmunity and extensive antigenic polymorphism among genetically separate *M. verrucosa*. The impressive polymorphism of H markers in this species is also confirmed by the incompatibility of all of some 280 intercolony graft combinations tested thus far within and between Onekahakaha, Kapoho and City of Refuge populations.

To what extent does allograft size influence direction, rate of appearance or degree of severity of cytotoxic reactions? Allografting in pairs at tissue mass ratios of 2:1, 4:1, and 8:1 was accomplished with the smaller piece the same size (9 cm<sup>2</sup>) in three experiments (Table 2). Within this range, graft dosage had little or no effect on the direction or timing of allograft reactivity. Initial cytotoxic reactions were scored with equal frequency on small or large grafts. All allograft reactions became bilateral in the same manner as control grafts of equal-size colonies. Very small pieces of *Montipora* seem more vulnerable to stress and disease in suboptimal conditions.

### Induction and duration of alloimmune memory

The occurrence of specific short-term memory was demonstrated by the second-set and third-party reactions evoked when appropriate repeat grafts were placed soon after initial graft pairs had responded incompatibly (Table 1). The questions arise: how long does such positive memory persist and how long does it take to induce such memory? The duration of alloimmune memory was tested

by second-set grafting pairs of corals at new interfaces at 2, 4, 8 and 16 weeks after separation from primary allografting. A 28-d period of primary contact was chosen to assure full sensitisation, since cytotoxic reactions were then underway in all graft pairs. Strong alloimmune memory was present in the second-set group grafted two weeks after first-set separation as shown by an early MRT of 10.7 (8.6–13.4) d (Table 3). This heightened reactivity had faded considerably in *Montipora* test-grafted after 4 weeks. At 8 weeks after first-set separation, specific memory was no longer detectible as evidenced by a MRT of 21.8 (16.1–29.4) d, quite similar to that of control first-set grafts. No further change was demonstrable after 16 weeks.

Possible early induction of memory was tested by disjoining initial allografts after 1, 2, 4 or 8 d of contact and regrafting the same pairs at new interfaces 3 d later. Eight coral pairs regrafted after only 1 d of allogeneic

Fig. 3 Logarithmic probability plots of first-set (●), second-set (×) and third-party (○) allograft reaction times of *M. verrucosa*. MRT difference between 1° and 2° grafts (22.0 and 11.6 d respectively) was highly significant; parallel slopes suggest same cytotoxic events occurred, but at different rates. Unrelated 3° allografts in lieu of specific 2° grafts displayed biphasic distribution of primary-type (3<sub>1</sub>°) and secondary-type (3<sub>2</sub>°) rejections.

**Table 2** Tests for influence of allograft size on cytotoxic reaction times in *M. verrucosa*

Allograft sizes*	No. coral pairs tested	Median reaction times (MRT) (d)†	Range of individual cytotoxic reaction times (d)
(1) 18 × 9 cm <sup>2</sup> (2 : 1)	8	18.2 (13.9–23.9) (7.3)	14–39
(2) 36 × 9 cm <sup>2</sup> (4 : 1)	8	20.9 (16.3–26.7) (7.8)	11–47
(3) 72 × 9 cm <sup>2</sup> (8 : 1)	8	24.4 (19.1–31.3) (9.1)	11–47

Graft dosage or size had little or no effect on the direction or timing of allograft reactivity.

\*Tissue mass ratios shown in parenthesis. Because the smaller piece was the same size (9 cm<sup>2</sup>) in all three experiments, the amount of allogeneic tissue in interfacial contact was also the same.

†Ranges in parentheses are 95% confidence limits; single numbers in parentheses below each entry are the standard deviations of the MRTs. Initial cytotoxic reactions were discernible with equal frequency on small or large grafts; all allograft reactions became bilateral in the same manner as control grafts of equal-size pairs.

contact yielded a MRT of 18.6 (15.5–21.6) d with a range of individual cytotoxic reaction times of 17–45 d. Similar results were obtained in three additional experiments with short-term presensitisation attempted for 2, 4 or 8 d. Individual cytotoxic reaction times ranged from 9–35 d, but only one test-allograft in each of these experiments exhibited an early reaction suggestive of induced immunity. Reaction time ratio tests showed that none of the four MRT's obtained was significantly different from the control first-set value of 22.0 d. Thus little or no pre-immunisation was conferred by short-term allogeneic contact in marked contrast to the potent immunity that resulted from contact for 28 d or longer. These results suggest that systemic immunisation requires longer than 8 d of cell-surface contact. Alternatively, any early immune memory induced seems to fade rapidly.

### Implications of immunoreactivity in lower invertebrates

In the light of earlier studies of advanced invertebrates, we were not surprised to find highly discriminating transplantation specificity in corals coupled to extensive polymorphism of allogeneic H markers probably abundant on cell surfaces. The decisive experiments were observable in nature, whereas our challenge was to quantitate the reactions in controlled laboratory conditions. The finding of specific alloimmune memory in coelenterates was

**Table 3** Duration of alloimmune memory in *M. verrucosa* after separation from primary allografting at 4 weeks

Time of second-set grafting (weeks after 1° separation)	No. coral pairs tested	Median reaction times (MRT) (d)*	Range of individual cytotoxic reaction times (d)
2	7	10.7 (8.6–13.4) (3.4)	9–17
4	8	15.3 (11.4–20.6) (6.8)	10–34
8	7	21.8 (16.1–29.4) (9.3)	12–38
16	7	20.1 (14.6–27.8) (9.1)	12–35

Strong alloimmune memory was present at 2 weeks, but this memory faded considerably by 4 weeks and was completely gone by 8 weeks after primary separation.

\*Ranges in parentheses are 95% confidence limits; single numbers in parentheses below each entry are the standard deviations of the MRTs.

unexpected, however, even though we realised that memory itself might well be an evolving characteristic in multicellular animals<sup>19</sup>. This supposition is now strengthened by the repeated demonstration of short-term memory in *Montipora* in this study. Further investigation of conditions that might favour long-term memory is desirable, because the absence of this characteristic could be a major distinguishing feature of lower metazoans.

The histopathological changes accompanying allocytotoxicity in *Montipora* have proved more difficult to interpret because the diversity of leukocytes or inflammatory cells associated with allograft reactions in higher animals is not evident in coelenterates. Moreover, appropriate techniques for fixation, decalcification and staining of coral tissues are not fully developed. Although we have many histological sections of *Montipora* allograft reaction zones at successive stages of incompatibility, cytotoxicity is obviously reflected only in tissue disruption, localised loss of cells in the immediate contact zone, and excessive mucus secretion. No lymphocytic or phagocytic-type cells, as found to infiltrate allografts in more advanced invertebrates<sup>3–5</sup>, have been detected thus far in our coral grafts. Although coelenterates including corals are endowed with leukocyte-type cells called amoebocytes<sup>20</sup>, their participation in allograft rejection reactions remains conjectural.

Elsewhere a two-component system of (1) specific H marker immunorecognition leading to (2) nonspecific cytotoxic reactions mediated by non-antibody proteins has been suggested as the essential basis for immunocompetence in multicellular invertebrates<sup>21</sup>. The specific induction phase is apparently contingent on polymorphic H receptors leading to activation or triggering of a nonspecific effector phase served by macromolecules with broadly toxic properties. Although specific cell-surface immunorecognition is characteristic of the solitary coral *Fungia*, the non-dialysable, xenocytotoxic molecule(s) secreted in response are nonspecifically reactive with diverse target cells<sup>11,17</sup>. This early but efficient form of immunoreactivity seems to have been retained during progressive evolution of immunocytes and diversification of functions.

The immunoglobulin (Ig) system of antibody-mediated immunity first appears at the level of chordates or fishes as an addition to the postulated H system of cell-mediated immunity already well-developed among invertebrates. Cooperation among lymphocytes and macrophages apparently led to progressive integration of the H and Ig systems eventuating in the immunoregulatory network characteristic of higher vertebrates<sup>21,22</sup>. The heterogeneity of classes of thymus-derived T lymphocytes serving numerous functions among vertebrates, including transplantation immunity, may involve distinctive H and Ig receptors<sup>23</sup>. Possibly the Ig molecules of vertebrates evolved from structurally similar H molecules<sup>24,25</sup> to provide physiologically complex animals with two immunorecognition systems.

We thank Drs Ian Johnston, Scott Linthicum, Satya Sood, Ms Lily Kam and Mrs Dorothy Hildemann for assistance. This investigation was supported by grants AI 13870 and RR 08073 from the USNIH, and University of Hawaii Research and Teaching Grant B182.

# Spatial configuration of mRNA 5'-terminus

Chong H. Kim & Ramaswamy H. Sarma

Institute of Biomolecular Stereodynamics, State University of New York at Albany, Albany, New York 12222

*Nuclear magnetic resonance investigation has revealed that the 5'-terminus m<sup>7</sup>G<sup>5'</sup>ppp<sup>5'</sup>Am of mRNA displays a spatial configuration in which the bases form stacked arrays. Details of the conformation as derived from coupling constants, shift trends and ring current considerations are discussed.*

THE 5'-terminal regions of a wide variety of mRNAs of eukaryotes contain an unusual sequence of nucleotides in which the terminal is 7-methyl-guanosine<sup>1-11</sup> (Fig. 1). Several studies<sup>10-15</sup> have shown that this sequence for the 5' termini of mRNAs is obligatory to carry out *in vitro* translation with fidelity.

To understand the structure-function relationships we have explored whether the uncommon constitution of the 5' termini endows any unique stereochemical features to mRNAs. The conformational properties of the 5' termini were investigated by studying the solution conformations of: (1), 7-methylated guanosine derivatives compared with the corresponding non-methylated analogues; (2), 2'-O-methylated nucleosides and the corresponding 5'-nucleotides compared with the non-methylated analogues; and (3), the dimer m<sup>7</sup>G<sup>5'</sup>ppp<sup>5'</sup>Am.

All materials used were commercial preparations. <sup>1</sup>H nuclear magnetic resonance (NMR) spectra were recorded at 270 MHz in the Fourier transform mode using systems described elsewhere<sup>16-18</sup>. All NMR spectra were analysed using a UNIVAC 1110 computer and LACON III. Figure 2 illustrates the observed and computer-simulated spectra of m<sup>7</sup>G<sup>5'</sup>ppp<sup>5'</sup>Am at two temperatures. The coupling constants data derived for the various monomers and the dimer were translated into conformational parameters using equations developed by Lee and Sarma<sup>19</sup> and Lee *et al.*<sup>18</sup> and the data are summarised in Table 1.

## Conformational properties of 7-methylated monomers

In general the ribose ring of common nucleosides and nucleotides at the examined pH and temperature exist as <sup>2</sup>E⇌<sup>3</sup>E equilibrium mixture with a bias of ≈ 60% for <sup>2</sup>E conformer (Table 1). Inspection of the ribose conformer populations for the non-methylated and methylated systems clearly reveals that 7-methylation has a decisive influence. The data show that this causes 13-24% increase in <sup>3</sup>E conformers and the increase closely follows the number of phosphate groups introduced. It is important to note that 7-methylated di- and triphosphates tend to populate in <sup>3</sup>E conformation and this is the first observed case in which purine 5'-nucleotides show a preference for <sup>3</sup>E pucker in

**Fig. 1** The sequence of mRNA at the 5'-region. The above sequence can be abbreviated as m<sup>7</sup>G<sup>5'</sup>ppp<sup>5'</sup>AmpA. Structures in which AmpA has been replaced with any of the common bases have been observed in mRNA. The conformational nomenclature  $\chi$ ,  $\psi$ ,  $\phi$ ,  $\omega$ ,  $\phi'$ ,  $\phi''$  and so on follow definitions according to IUPAC-IUB. In the present paper a letter 'c' is inserted to distinguish between the cap region and the AmpA region. Thus  $\chi_c$  stands for sugar base torsion of m<sup>7</sup>Gp- and  $\chi_1$  and  $\chi_2$  for the Amp- and -pA parts respectively. Non-standard abbreviations such as G<sup>5'</sup>p, G<sup>5'</sup>pp are used for 5'-GMP, 5'-GDP and so on in accordance with their wide use in the original papers<sup>1-11</sup>.

Fig. 2 The observed 270-MHz  $^1\text{H}$  NMR spectra of  $m^7\text{G}^{5'}\text{ppp}^{5'}\text{Am}$  at  $5^\circ\text{C}$  (c) and  $80^\circ\text{C}$  (e). Both spectra were analysed by computer simulation of  $m^7\text{G}^{5'}\text{p}$ - (a and g) and  $-p^{5'}\text{Am}$  parts (b and h) separately (a and b at  $5^\circ\text{C}$  and g and h at  $80^\circ\text{C}$ ) and combining them to produce complete simulation at  $5^\circ\text{C}$  (d) and at  $80^\circ\text{C}$  (f). The chemical shifts are Hz relative to tetramethylammonium chloride.

aqueous solution. In the 7-methylinosine series 5'-phosphorylation has no effect on ribose conformation, in the contrast to the 7-methylguanosine series. Changing the ionisation state of the phosphate causes only a slight shift to  $^3\text{E}$  pucker for  $m^7\text{G}^{5'}\text{p}$ . In the case of di- and triphosphate this has an opposite effect, that is,  $^2\text{E}$  population increases. With respect to the common derivatives only the diphosphates are sensitive to ionisation changes.

The data indicate that irrespective of whether mono-, di- or triphosphate, or whether 7-methylated or not, all nucleotides show an overwhelming preference for  $g'g'$  orientation ( $\phi_c = 180^\circ$ ) about  $\text{C}5'-\text{O}5'$ . There is, however, a drastic change on conformational preference about  $\text{C}4'-\text{C}5'$  in going from 7-methylated nucleoside to corresponding nucleotide. The population of  $gg$  orientation ( $\psi_c = 60^\circ$ ) significantly increases on 5'-mono-, di- or triphosphorylation of 7-methylguanosine. A possible reason for this overwhelming increases in  $gg$  population is the electrostatic interaction between the positively charged N7 and the negatively charged phosphate groups. In the  $gg$  conformation the distance between the phosphate oxygens and N7 is minimum compared with that in the alternate  $gt$  ( $\psi_c = 180^\circ$ ) and  $tg$  ( $\psi_c = 300^\circ$ ) conformers. The phosphorus chemical shift data summarised in Table 2 clearly substantiate this electrostatic interaction. Particularly noteworthy is the substantial difference in chemical shifts between the  $\gamma$  phosphorus of  $m^7\text{G}^{5'}\text{ppp}$  and  $\text{G}^{5'}\text{ppp}$ .

It should be noted that  $m^7\text{G}^{5'}\text{p}$ ,  $m^7\text{G}^{5'}\text{pp}$  and  $m^7\text{G}^{5'}\text{ppp}$  exist

with almost exclusive preference for the  $gg$  orientation about  $\text{C}4'-\text{C}5'$ . This presents a drastic contrast to the situation in  $\text{G}^{5'}\text{p}$ ,  $\text{G}^{5'}\text{pp}$  and  $\text{G}^{5'}\text{ppp}$ , all of which exist as a conformational blend in which the  $gg$  population range from 67–77%, the remaining being the alternate  $gt$  and  $tg$  conformers. This is the first time a nucleotide in aqueous solution has been shown to exist with a rigid geometry about  $\text{C}4'-\text{C}5'$ . The data thus point out the impact of 7-methylation on the conformational freedom about  $\text{C}4'-\text{C}5'$  bond in the guanosine 5'-nucleotides. This is a general phenomenon associated with 5'-purine nucleotides and not something endemic to the guanosine system is illustrated by the data on  $m^7\text{I}$  and  $m^7\text{I}^{5'}\text{p}$  (Table 1).

X-ray and NMR data and theoretical calculation on mono- and dinucleoside monophosphates (see ref. 18 and refs therein), have shown that the preferred glycosidic torsion in these systems lie in the anti domain. In the 7-methylguanosine series the anti domain is congenial for the electrostatic interaction discussed above.

### Conformational properties of 2'-O-methylated monomers

The data in Table 1 for the 2'-O-methylated nucleosides and nucleotides reveal that at the monomer level 2'-O-methylation has only very little influence on the conformational preferences of the ribose ring,  $\text{C}4'-\text{C}5'$  and  $\text{C}5'-\text{O}5'$  bonds. They, in general, exist as a conformational blend in which  $^2\text{E}$  pucker,  $gg$  and  $g'g'$  conformations are preferred. The influence of the ionisation of phosphate on the chemical shifts of base and ribose protons (data not given) reveal that in this system the base occupies anti domain.

### Conformational properties of the dimer $m^7\text{G}^{5'}\text{ppp}^{5'}\text{Am}$

The conformational parameters (Table 1) indicate that  $m^7\text{G}^{5'}\text{p}$ - and  $-p^{5'}\text{Am}$  of the dimer show a significant preference to orient the  $\text{C}4'-\text{C}5'$  and  $\text{C}5'-\text{O}5'$  backbone in the classically staggered conformation in which  $\psi = 60^\circ$ ,  $\phi = 180^\circ$ . But,  $m^7\text{G}^{5'}\text{p}$ - component prefers  $^3\text{E}$  sugar pucker and  $-p^{5'}\text{Am}$  component prefers  $^2\text{E}$  sugar pucker. Comparison of the conformational data for the dimer with that of the monomers at pH 5 (Table 1) clearly indicates that with respect to the local conformations about the sugar ring,  $\text{C}4'-\text{C}5'$  and  $\text{C}5'-\text{O}5'$  bonds the monomers essentially conserve their conformation in the dimer. There is a small but real shift towards  $^3\text{E}$  pucker in the dimer for the  $m^7\text{G}^{5'}\text{p}$ - part, however. This small shift may indicate a reduction in the  $\chi_c$  of the dimer compared with that of the monomer, because of the conformational nexus between ribose pucker and  $\chi_{\text{CN}}$  (ref. 18).

Information about the molecular topology and intramolecular order of the dimer can be obtained from comparison of the chemical shift data for monomers and the dimer. These dimerisation data are presented in Table 3. The data clearly show that the two nucleotidyl units at the 5' ends of the triphosphate bridge interact with each other, changing the effective field felt at the various protons. As a result of this interaction the chemical shifts of the two residues undergo drastic changes. The protons which show negligible changes are only  $\text{H}4'$ ,  $\text{H}5'$  and  $\text{H}5''$  of the  $m^7\text{G}^{5'}\text{p}$ -residue. The  $\text{H}5'$  and  $\text{H}5''$  of the  $-p^{5'}\text{Am}$  residue undergo shifts to

Fig. 3 The two perspectives, drawn using ORTEP, of  $m^7\text{G}^{5'}\text{p}$ . The left one shows the 'B' side of purine and the right one the 'A' side. The ribose is  $^3\text{E}$ ,  $\psi = 60^\circ$ ,  $\phi = 180^\circ$  and  $\chi_c = 60^\circ$ . This is the most preferred conformation of  $m^7\text{G}^{5'}\text{p}$ .

Concentration is 0.02–0.07 M for the monomers except for G(0.004 M) and 0.007 M for m<sup>7</sup>G<sup>5'</sup>ppp<sup>5'</sup>Am. The temperature in all cases was 19 ± 1 °C unless otherwise stated.

lower field. The remaining protons of both residues are shifted to higher field by as much as 60 Hz. From the observation that H8 and H2 of the -p<sup>5'</sup>Am moiety and 7-CH<sub>3</sub> group of m<sup>7</sup>G<sup>5'</sup>p- moiety are shifted to higher field it is immediately apparent that the two aromatic systems interact with each other as probably in a parallel stacking.

It should be emphasised that the interaction between bases takes place while the individual nucleotidyl units maintain very similar conformation for ribose, C4'-C5' and CS'-OS' bonds as in the monomers. Hence this intramolecular stacking interaction must be made feasible by torsional variation around the phosphodiester bonds of the triphosphate bridge. To describe the stacking possibilities between the two ring systems it is necessary to label the sides of purine moieties by the letters A and B as has been done before<sup>20–22</sup>. These are shown in Fig. 3 for m<sup>7</sup>G<sup>5'</sup>p-. There are four possible types of stacking: (1) A-A stacking. A surface of m<sup>7</sup>G<sup>5'</sup>p- moiety faces the A surface of -p<sup>5'</sup>Am moiety (Fig. 4a). (2) A-B stacking. A surface of m<sup>7</sup>G<sup>5'</sup>p- moiety faces the B surface of -p<sup>5'</sup>Am moiety (Fig. 4b). (3) B-A stacking. B surface of m<sup>7</sup>G<sup>5'</sup>p- moiety faces the A surface of -p<sup>5'</sup>Am moiety (Fig. 4c). (4) B-B stacking. B surface of m<sup>7</sup>G<sup>5'</sup>p- moiety faces the B surface of -p<sup>5'</sup>Am moiety (Fig. 4d).

In A-A and B-B stacking the O1' of both ribose rings are oriented in opposite direction whereas in A-B and B-A stacking they are oriented in the same direction (Fig. 4). The four stacking arrangements depicted in Fig. 4 are generated while maintaining the same conformation for the ribose rings, C4'-C5' and CS'-OS'

bonds, and the only changes are in  $\chi_c$ ,  $\chi_1$ ,  $\omega C_1$ ,  $\omega' C_1$ ,  $\omega C_2$ ,  $\omega' C_2$ ,  $\omega C_3$  and  $\omega' C_3$ .

The observation that the base protons of -p<sup>5'</sup>Am moiety and 7-methyl group of m<sup>7</sup>G<sup>5'</sup>p- moiety are shielded (Table 3) can be rationalised on the basis of any of the above stacked structures or on the basis of a blend of all the four forms. One should, however, be able to make a distinction by following the shift trends of interior protons such as H1', H2', H3', H4', H5', and H5". The shifts of H5' and H5" could be affected by torsional changes in the phosphate backbone as a dimer is formed from the monomer, and hence are of little use in the determination of stacking interactions from ring current considerations. The H1' chemical shift of both residues will be highly sensitive to  $\chi_{CN}$  variation and the observed upfield shift of H1' (Table 3) is an indication of reduction in  $\chi_{CN}$ .

**Table 2** Chemical Shift data (Hz) of phosphorus in guanosine derivatives

Shifts are given relative to internal trimethylphosphate, (CH<sub>3</sub>O)<sub>3</sub>OP. Concentration is 0.05 M, pH 7.0 at 19 ± 1 °C. 40.5 MHz NMR system.

Fig. 4 The four basic stacked arrays A-A (a), A-B (b), B-A (c) and B-B (d) possible for  $m^7G^{5'}ppp^{5'}Am$ . The perspectives were generated using ORTEP. In all the projections the ribose of the  $m^7G^{5'}p$ - part is  $^3E$  and that of the  $-p^{5'}Am$  part is  $^2E$ , further  $\psi_c = 60^\circ$ ,  $\phi_c = 180^\circ$ ,  $\phi_1 = 180^\circ$ ,  $\psi_1 = 60^\circ$  and  $\phi'' = 180^\circ$ . These are the experimentally observed preferred values. The values for  $\chi_c$  and  $\chi_1$ , as well as those for  $\omega C1/\omega' C1$ ,  $\omega C2/\omega' C2$ ,  $\omega C3/\omega' C3$  cannot be obtained directly from NMR data because of the lack of appropriate nuclei to produce the desired coupling constants. But the data clearly reveal that the bases are in the antidiagonal and the orientation of the phosphodiester bonds allow stacking interactions. A search in the conformation space produced a set of values for  $\chi_c$ ,  $\chi_1$ ,  $\omega C1/\omega' C1$ ,  $\omega C2/\omega' C2$  and  $\omega C3/\omega' C3$  which can generate the four possible stackings.

(refs 23, 24) on dimerisation. This is anticipated because dimerisation and stacking will necessitate the readjustment of  $\chi_{CN}$  in the dimer compared to the values in the monomers. It should be noted that in both dimer and monomers the base prefers anti domain but the magnitude of  $\chi_{CN}$  in the dimer is smaller than that in the monomer. NMR methodology cannot precisely determine the magnitude of  $\chi_{CN}$  but can only provide relative changes<sup>24</sup>. If the value of  $\chi_{CN}$  in the monomer is between  $50^\circ$  and  $60^\circ$ , the value in the dimer will be between  $30^\circ$  and  $40^\circ$ . Hence, one cannot use the shift trends of  $H1'$  to monitor the stacking interactions. But, the observation that  $H2'$  and  $H3'$  of  $m^7G^{5'}p$ - and  $-p^{5'}Am$  have undergone significant shielding to higher fields can be rationalised only on the basis of the presence of significant populations of A-A stacking. Inspection of perspectives (Fig. 4a-d) clearly reveals that only in an A-A stack these four protons lie inside of the stack. Thus  $H2'$  (see Table 3) and  $H3'$  of  $m^7G^{5'}p$ - moiety can be shielded

by the adenine of  $-p^{5'}Am$ , conversely  $H2'$  and  $H3'$  of  $-p^{5'}Am$  moiety can be shielded by the guanine ring of  $m^7G^{5'}p$ -. This mutual shielding is possible only in an A-A stack. The observed difference in the magnitude of shielding between the sets of  $H2'$  and  $H3'$  protons of two moieties is merely a reflection of the difference in the ring current fields of adenine and guanine moieties<sup>26</sup>. The ring current shielding abilities of guanine are less than that of adenine<sup>25,26</sup>. In the present case the guanine ring contains positive charge and this will further dilute the effect of guanine. The data in Table 3 clearly show that the adenine shields the  $H2'$  and  $H3'$  of  $m^7G^{5'}p$ - considerably more effectively than guanine shields the  $H2'$  and  $H3'$  of  $-p^{5'}Am$ . This is indeed expected.

Because of the inherent flexibility of the various phosphodiester linkages, in aqueous solution it may be that the dimer  $m^7G^{5'}ppp^{5'}Am$  exists as a conformational blend of the various stacked arrays and extended forms. Our major conclusion is that among the

‡GH8 exchanges with  $D_2O$  and could not be located.

Note that even though the data indicate significant high field shift for  $H2'$ , the theoretically projected<sup>25,26</sup> shielding of  $H2'$  originating from stacking interactions in A-A stacks should be larger than what is observed. This is because, this high field shift is internally compensated by the down-field shift<sup>23</sup> of  $H2'$  caused by reduction in  $\chi_c$  associated with  $^3E$  sugar pucker.

various conformational possibilities in aqueous solution the A-A stack predominates and the molecule has an inherent proclivity to form A-A stacked arrays. The temperature data on  $m^7G^{5'}ppp^{5'}Am$  summarised in Table 3 closely parallel the dimerisation trends and these observations are essentially in agreement with the findings of Ts'o and coworkers<sup>27</sup> that elevation of temperature causes de-stacking and at higher temperatures the dimer tends to approximate to monomer conformations.

## Evidence for a 39-d period in Cyg X-1

THE detection of a 39-d period in Cyg X-1 (HDE226868), as seen in the ultraviolet (ultraviolet-filter) polarisation<sup>1</sup>, would have at least one interesting interpretation, that of a third-body orbital period (M. Milgrom and J. Shaham, personal communication). We report here the result of long-term monitoring of the optical polarisation of Cyg X-1<sup>2</sup>, which has been in progress since 1974 at Pine Mountain Observatory, Oregon. Up to early August 1977, over 225 nights of ultraviolet-filter data were obtained. Power spectra of the ultraviolet-filter polarisation computed in March 1977 suggested a peak at the approximate period 39 d, common to the separate power spectra of our two instrumental Stokes parameters<sup>2</sup>  $Q$  and  $U$ . The amplitude of the feature corresponds to a peak-to-peak polarisation variation of about 0.25%. The  $Q$  and  $U$  variations proved to be coherent with each other and to be of a rectilinear type, describable as a simple variation along a certain rotated Stokes parameter  $Q_0$ , defined approximately by  $Q_0 = p \cos[2(\theta - 117^\circ)]$ . The normalised conjugate parameter  $U_0 = p \sin[2(\theta - 117^\circ)]$  shows no significant variation at the 39-d period.

Cyg X-1 has an interstellar polarisation of roughly 5%, on which variations of the order of  $\pm 0.3\%$  are superimposed. The variability is partly or largely random in character; the isolation of periodicities, therefore, requires a long-term programme. We have also recorded a slow secular change in  $p$ , the degree of polarisation, averaging about  $0.00047\% \text{ d}^{-1}$  in the ultraviolet; this has amounted to a shift from an average  $p = 4.25\%$  in 1974 to  $4.55\%$  in 1977.

Figures 1 and 2 show power spectra of the ultraviolet-filter polarisation, computed by the bin method<sup>2</sup>, using data from 192 nights spanning the interval September 1974-June 1977. The two spectra in Fig. 1 are of the  $Q_0$  parameter, in which the 39-d effect is most evident. Figure 2 shows the power spectra of  $Q_0$  and  $U_0$  using the slope-corrected data after a mild weighting, in which all data entries (nights) which exhibit excursions  $\Delta Q$  or  $\Delta U$  exceeding 0.7% have been assigned relative weights of 0.5 (15 nights are thus de-weighted).

The 39-d peak in  $Q_0$  is the highest peak in all of our power spectra, apart from very long-period structure ( $P \geq 400 \text{ d}$ ) when the secular slope is not removed as in Fig. 1a. In later results, using 225 nights of data, the contrast of the 39-d feature has improved. A very rapid improvement cannot be expected.

Statistical aspects of the apparent 39.2-d periodicity are summarised in Table 1, which is based on an analysis made with a

packaged statistical program. The latter performs linear regression and yields various data such as  $F$  values. We used a multi-function fit to the raw data including: (1) a slope term, to account for the secular change in polarisation; (2) the predominant 39.2-d sinusoid; and sometimes (3) a harmonic, of period  $39.2 \text{ d}/n$ , where  $n$  is an integer. (The case  $n=0.5$  is also included in Table 1.) The likelihood of a null hypothesis for each frequency component, of arbitrary phase but pre-assigned period, is given in column 3. Those probabilities must be multiplied by the number of statistically-independent periods, that is by  $N/2$  where in this case

Fig. 1 Power spectra of Cyg X-1 ultraviolet-filter polarisation, based on 192 nights from September 1974 to mid-June 1977. (One data point per night is taken, involving 1-3 h of integration including calibrations.) Computed by simple bin-averaging method of Kemp *et al.*<sup>2</sup>. Such power spectra have slightly poorer signal-to-noise ratios than spectra computed from linear regression, but are less expensive in computer time. Scan uses 1,000 discrete frequencies, six bins. *a*, raw data; *b*, computed from data with secular slope ( $\Delta p = +0.0005\% \text{ d}^{-1}$ ) removed thus suppressing the structure at very long periods ( $> 200 \text{ d}$ ). Parameter  $Q_0$  has maximum amplitude at 39.2 d. In all the figures, ordinate is proportional to power, that is to the squared Fourier amplitudes of the polarisation in per cent; abscissa is linear in frequency (inverse period).

Fig. 2 Power spectra with slope removed, and with data slightly weighted; 19 points with  $a, \Delta Q$  or  $b, \Delta U$  (variations from means) given weights 0.5, all others given weights unity. A very slight improvement is noticed in the apparent signal-to-noise ratio. Both Stokes parameters are shown.

$N=192$ . We must also multiply by 2, to account for the two Stokes parameters  $Q_0$  and  $U_0$ . Unbiased probabilities for a random-noise hypothesis are thus given in column 4.

From this analysis, and other criteria, we have concluded that the 39.2-d periodicity is real with a probability which now exceeds 97%.

Of the harmonics, only the fourth (of period 9.8 d) seems to be appreciable. In Table 1 the low amplitudes at 2.8 d and 5.6 d, are of special interest the latter being the well-known binary orbital period.

Figure 3 shows an amplified trace of the  $Q_0$  power spectrum in the vicinity of 39 d. A least-mean-squares fit to the function  $(A \sin \Delta v / \Delta v)^2$  has been made. We find a best-fit period of 39.22 d for the bin-type power spectrum, and 39.30 d for the linear-regression points—or an average of about 39.26 d. To three significant figures<sup>3</sup> the binary period of Cyg X-1 is 5.60 d. We thus contemplate the ratio  $39.26/5.60 = 7.01$ . That is, the 39.2-d period is very likely the exact seventh multiple of the binary period.

Because of the almost integral relationship just shown, one might suspect that the 39-d pattern is an aliasing effect of some kind, but this is unlikely. The test power spectra obtained by applying pure sinusoids to our sampling times have negligible side lobes, less than 1/5 as strong as the central peaks, as we have tested for 39.2-d, 5.6-d and 2.8-d fundamental periods; and furthermore, the Fourier amplitudes at 5.6 and 2.8 d in the observed power spectra are very weak. A confusion with aliases having periods very close to 1.0 d, namely the periods  $(1.0 \text{ d} \pm 1/39.2 \text{ d})$ , cannot be

ruled out, because our observations are always separated by about 1 d or more. We discount that possibility.

As yet the 39-d periodicity has not been detected in other properties. A search of the X-ray flux records does not show such a period (S. S. Holt, and E. N. Walker, personal communications); but the X-ray variability is known to have at best only a tenuous connection with the optical behaviour<sup>4</sup>. Virtually all of the optical photometry of Cyg X-1 has been performed in blue filter (blue light). There is no indication of a 39-d period in the blue photometry (E. N. Walker, and I. G. Nolt personal communications). On the other hand, it is likely that the 39-d effect is

Fig. 3 Local power spectrum,  $Q_0$  parameter, around 39-d period. Jagged curve<sup>2</sup> is generated by bin-analysis program; circle points were obtained one at a time from multiple regression program including a slope plus sine and cosine (for each period). A curve fit to the diffraction-like function is shown.

wavelength-dependent and is absent in the blue-visible: the ultraviolet-blue-visible polarimetry of 1975<sup>2</sup> indicate  $Q_0$  amplitudes of  $\leq 0.06\%$  in blue and  $\leq 0.08\%$  in visible. Ultraviolet photometry, currently under investigation at our observatory, may answer the question of a photometric counterpart of the polarisation period.

We thank E. N. Walker, E. T. Bolton, S. S. Holt, I. G. Nolt, M. Milgrom, and J. Shaham for helpful discussions. Our work is supported by NSF grant MPS 75-19754.

## Possible 39-d polarisation period in Cyg X-1

KEMP<sup>1,2</sup> has reported that the power spectra of the  $Q$  and  $U$  Stokes polarisation parameters, for the  $U$  band radiation from Cyg X-1, show a  $\sim 3\sigma$  peak at  $39.26 \pm 0.10$  d. The peak was found to represent a modulation in which  $Q$  and  $U$  vary, in phase, at 0.27% peak-to-peak total polarisation. While this was reported to be the strongest  $U$  band periodicity in the frequency range considered, it was not found in the  $B$  and  $V$  bands (ref. 3 and J. Kemp, personal communication). Further

observations are necessary to set limits on this modulation for the various radiation bands. This letter suggests that such variable polarisation component may arise from those optical photons which, after being radiated by the disk, are Thomson scattered into our line of sight by the flared material at the outer parts of the disk and in the incoming flow<sup>4</sup>. Details will be published elsewhere<sup>5</sup>. Here we note that, with a favourable ratio of electron scattering opacity to absorption opacity and with a scattering depth  $\tau_{es} \sim 1$ , such scattering can polarise the photons to a high degree ( $\sim 20\%$ ); we also note, that the in-phase variability of  $Q$  and  $U$  can come about if the azimuthal structure of the scattering region does not have a 39.2-d variation (for example, if the disk is always axially symmetrical), while the  $r, z$  structure does have sufficient variability to change the amount of scattered photons relative to the total flux and hence to produce a variation in total polarisation.

Matter from the primary which flows through L1 to join the outer disk assumes, on a Keplerian time scale, such constant azimuthal structure, which we may call 'the scattering rim'.  $r, z$ -Structural variability can then come about by a modulation in L1 overflow. The latter can be induced by tidal interaction with an eccentric, 39-d periodic motion of a third, light, star around the Cyg X-1/HDE 226868 system, in a way similar to that suggested previously for the Her X-1/HZ Her system<sup>6</sup>.

The L1 point for the binary system is located  $\sim 10\text{--}16 \times 10^{11}$  cm from the compact object, for the accepted range of binary masses. If the rim is located at a distance of  $r_{11} \times 10^{11}$  cm and, for simplicity, extends over  $0.2 \times 10^{11}$  ( $\alpha/0.2$ )  $r_{11}$  cm in the  $r$  and  $\pm z$  directions, then its transversal optical scattering depth is  $\tau_{es} \sim 3(\alpha/0.2)^{-1} \psi r_{11}^{-2} \dot{m}_{-9}$ , where  $\dot{m}_{-9}$  is the average accretion rate, in units of  $10^{-9} M_{\odot} \text{yr}^{-1}$ , and  $\psi$  is the mass of the 'rim' in units of the total mass accreted during a 39-d period. In steady state, the inward drift time of the 'rim' is of order  $\sim 39$  d and we expect  $\psi \lesssim 1$  for a large flow modulation. Due to the non-hydrostatic nature of the rim<sup>7</sup> and its heating<sup>8</sup>, we expect  $\alpha$  to be larger than the angular size calculated for hydrostatic disks. The condition  $\tau_{es} \sim 1$  thus seems to be compatible with current understanding of disk and mass flow (when  $\tau_{es} > 1$ , (but not  $\gg 1$ ) polarisation by backscattering could still occur).

For U band photons,  $\kappa_{es}$  dominates at densities

$$\rho < 2 \times 10^{-10} T_4^{1/2} \text{ g/cc} = \rho_c \quad (1)$$

where  $T_4$  is the temperature in  $10^4$  K. On rewriting equation (1) as  $T_4 \geq 0.5 r_{11}^{-2} (\alpha/0.2)^{-2} \tau_{es}^2$ , we note that this condition is also likely to be satisfied, since rim cooling drops sharply when  $T_4 < 1$  due to the decreasing ionisation, and since the rim is being constantly heated by the incident X-ray flux and the jet-disk shock.

Due to uncertainties in efficiency and total luminosity of Cyg X-1 we can estimate only roughly the  $U$  luminosity,  $L_{u,d}$ , in the direction of the rim. To produce a 0.27% total polarisation with 20% scattering polarisation we must have  $L_{u,d} \sim 0.1(\alpha/0.2)^{-1} L_{u,p} \sim 0.2(\alpha/0.2)^{-1} L_{x,d}$ , where  $L_{u,p}$  is the primary luminosity and  $L_{x,d}$  is the 2–6 keV X-ray luminosity<sup>9</sup>. Since most of the optical luminosity is due to X-ray heating<sup>10</sup>, we do expect a suppression of  $B$  and  $V$  rim scattered flux, hence of 39-d  $B$  and  $V$  polarisation modulation, relative to the  $U$  band. This is because such optical surface emission has a strong limb brightening effect<sup>11</sup>, especially at glancing angles, and may develop a marked inverted Balmer jump (higher intensity for wavelengths below the Balmer edge). Some support for this property of heated surface emission is furnished by indirect observations of the continuum emission from the disk in SMCX-1 (ref. 12).

The existence of a modulated rim structure can be tested by further observations: The hard X-ray ( $> 10$  keV) intensity and polarisation should be modulated at 39 d, with respective peak-to-peak amplitudes of 70% and 15%, where  $a$  is the albedo. The average polarisation for  $a \sim 0.2$  and  $a \sim 0.5$  is comparable to the predicted<sup>5,13</sup> and observed<sup>14</sup> constant

polarisation of hard X rays. The corresponding amplitudes for soft X rays should be smaller due to their increased absorption. Furthermore, a 0.015 mag peak-to-peak 39 d modulation in  $U$  intensity is expected, with a smaller amplitude for the  $B$  and  $V$  radiations. All of these modulations should occur in phase, and, to the extent that the rim structure changes during a high-low transition in Cyg X-1<sup>15</sup>, their amplitudes should change too.

The existence of a third star can be further tested by observations of additional periodicities in intensities and polarisations. Aside from smaller amplitude binary or half binary periods, periods associated with the variable tidal forces are expected. The latter form a large set of sums of integral multiples of  $\frac{1}{2}(\omega_b - \omega_3)$  and the 39 d frequency, where  $\omega_b$  is the binary frequency and the  $\omega_3$ 's are instantaneous frequencies of the third stellar motion. Such tidal modulations will only show up as flow modulations if the time responses at L1 and during the free-fall, circularisation and inward rim diffusion are sufficiently small. The proximity of the observed 39.2-d period to an integral multiple of half a binary period ( $14 \times 2.8$  d) may be due to the eccentricity of the binary orbit or may be related to the forbidden binary phase for X-ray turn-ons in Her X-1 (see ref. 6). We also expect longer periods, associated with modulations in binary eccentricity and precession of its nodes.

Similar polarisation measurements for the Her X-1/HZ Her system may distinguish between models suggested for its 35-d period. For example, if  $U$  and  $Q$  are found there too to vary in phase, this may rule out a precessing disk model.

## The 39-d period in Cyg X-1

KEMP *et al.*<sup>1,2</sup> recently claimed to have discovered a 39-d period in the linear polarisation of the U band light for HDE 226868, the optical counterpart of Cygnus X-1. Within the errors their period is exactly seven times the 5.60-d orbital period of this binary system. Based on this result Milgrom and Shaham<sup>3</sup> produced a model for Cyg X-1 involving a three-body system in which the third component is in a 39-d orbit about the 5.6-d X-ray binary system. This note draws attention to the absence of a 39-d period in other data on this star.

Walker and Rolland Quintanilla<sup>4</sup> have recently completed an analysis of 349 nights of B band data obtained in 1972–76.

Two methods were used to search these data for possible periods. The first was based on the method of Lafler and Kinman<sup>5</sup> and the second on the Fourier technique developed by Grey and Desikachary<sup>6</sup>. Neither method shows any evidence for a period of 39 d or at one half or double that period. A realistic upper limit can be set to any modulation of the blue light of this star at any of these periods of 0.001 mag., that is, 0.1%. This has to be compared with the modulation at 2.8 d (half the orbital period) of over 2%.

A literature search for periods in 215 radial velocities for this star<sup>7-13</sup> allows us to put an upper limit on any 39-d period of  $<10 \text{ km s}^{-1}$  compared with over  $60 \text{ km s}^{-1}$  for the variations with the 5.60-d orbital period.

We have also searched the X-ray flux measurements for periods using the Grey and Desikachary<sup>6</sup> method. The data are from the All Sky Monitor (2–6 keV) and the Sky Survey Instrument (2–18 keV) on the Ariel V satellite. Combined data from both experiments give almost complete coverage at one satellite orbit interval ( $\sim 100 \text{ min}$ ) over the 590 d before March 1977 including both high and low states of X-ray activity. The high state data are characterised by massive (approximately fourfold) modulation of an apparently random character and an upper limit of  $\sim 10\%$  is the best that can be placed on any 39-d modulation. But, the much more extensive low state data, where the overall modulation is much smaller, give an upper limit of  $\sim 3\%$  to any 39-d modulation. In both cases the power at  $\sim 39 \text{ d}$  is significantly less than that at nearby frequencies and in neither case does the power spectrum suggest any significant 39-d period.

We believe that the reality of this period and the subsequent model must be in doubt. This is because of the marginal nature of the evidence for a 39-d period in the U-band polarimetry and the upper limits to modulation with this period, or its nearest harmonics, in the B band, radial velocity and low state X-ray data.

## Mercury in surface waters of seas around the United Kingdom

A SURVEY of the concentration of mercury in the surface waters of the seas around the UK, has been made as part of the Ministry of Agriculture, Fisheries and Food's overall programme of investigation into the distribution of heavy metals in the marine environment. Using a cold vapour–

gold trap method on board a research vessel, thus obviating the necessity to store the samples with consequent problems of loss and/or contamination, both 'reactive' and 'total' mercury concentrations have been measured. The results reported here show clearly the major sources of emission. The possible reasons for differences between these results and those of some other investigators are also discussed.

Preston *et al.*<sup>1</sup> have described a pilot survey carried out to measure the concentrations of selected heavy metals in seawater, suspended matter and biological indicators from British coastal waters. Since then analytical methods have been refined and more surveys carried out. Recently, because of the significance of possible mercury pollution and its effect on man, surveys have been carried out to measure the mercury levels in UK coastal waters. Because of the problems of loss of mercury and contamination of samples with mercury<sup>2,3</sup>, we have analysed such samples immediately after collection. The technique described here is designed for use on board a research vessel.

The sample, collected either by plastic bucket or Niskin bottle and not filtered, is immediately transferred to a 2.5 l glass bottle, previously checked for contamination, and acidified by adding 10 ml of concentrated sulphuric acid per l of sample. A 100 ml aliquot of this is taken for analysis. The mercury is swept from solution, after reduction with stannous chloride, by bubbling nitrogen through the sample and collecting the mercury on gold wire chips. The mercury is then determined by heating the gold to high temperature, and sweeping the mercury through a Coleman MAS 50 mercury analyser. The resultant absorption peak is recorded on a strip chart recorder set at about a  $\times 30$  expansion of the MAS 50 output. The peak height is measured and compared with a standard calibration line produced either by internal standardisation, or addition of mercury standards to a previously reduced sample. The practical detection limit is about  $0.5 \text{ ng l}^{-1}$  and the coefficient of variation at  $1 \text{ ng l}^{-1}$  level is about  $\pm 10\%$ . The analysis takes 10 min from the time the sample arrives on deck.

The results of the analysis of samples taken on two cruises during 1976 are given in Fig. 1. The cruises were carried out between 2 and 16 January, a period of extremely stormy weather, and between 25 May and 14 June, a period of prolonged calm weather, when the suspended load was abnormally low. The areas have been chosen arbitrarily, and the individual high spots have not been included in the calculation of the mean value for each area. Figure 2 shows contours derived from the data summarised in Fig. 1 and the positions of the sampling stations. The main areas of mercury contamination are apparently in the Thames Estuary, Liverpool Bay, the area off the Humber Estuary and, to a lesser extent, the Bristol Channel and the mouths of the Rhine and Elbe rivers. The data from areas A, B, C, D, H and L do not show any clear out contouring.

The exact forms in which mercury exists in seawater are in doubt, but it is likely that as well as being present as an anionic chloride complex, it will also be complexed by organic material both in solution and in suspended matter. How filtering affects the mercury content of the sample is uncertain, so an environmentally artificial, analytical delineation between 'reactive' and 'total' mercury has been conveniently adopted. The 'reactive' mercury is defined as that which is available for reduction by stannous chloride from samples acidified to about pH 1. The 'total' mercury is that made available to reduction by stannous chloride, following oxidation of the sample with ammonium persulphate. Chlorine, produced during the oxidation, interferes with the measurement, and is removed by a ferrous sulphate scrubber after the reduction step. The mean values obtained for total mercury levels are given in Table 1. The values for the areas H, I and J are not available due to difficulties experienced with the oxidation stage during the early part of each

cruise. In every case an increase in the mercury measured after oxidation was observed.

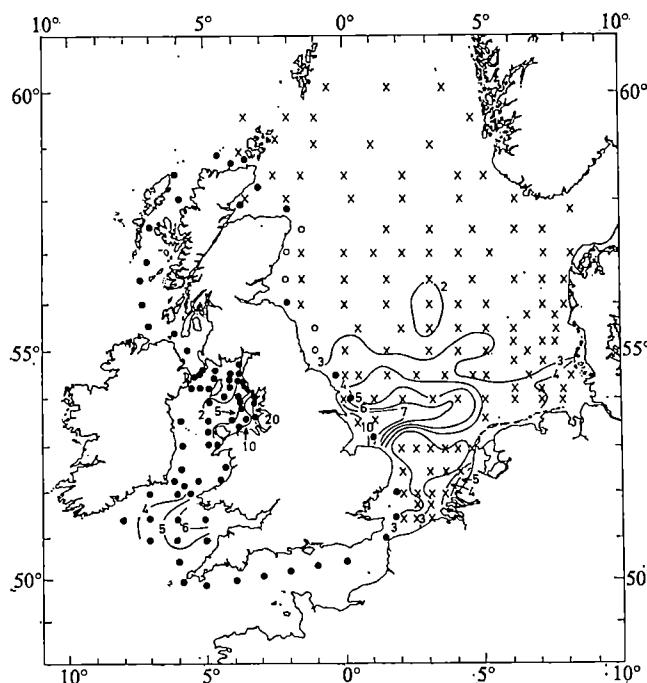

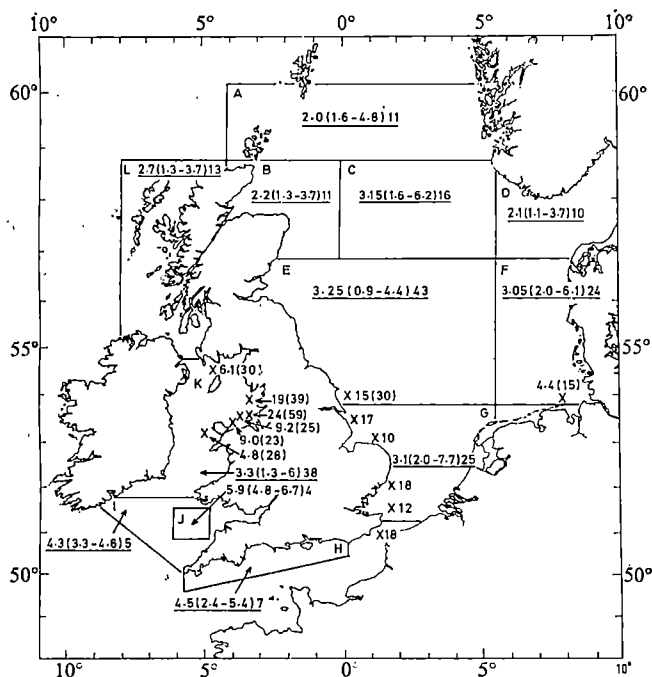

Samples collected in the open ocean areas, acidified and analysed immediately, stored for 1 month in glass and then reanalysed, gave similar results for both the 'reactive' and the 'total' mercury. One sample, however, collected during 1975, in an area of high suspended load and high mercury contamination gave results of  $8 \text{ ng l}^{-1}$  and  $73 \text{ ng l}^{-1}$  for 'reactive' and 'total' mercury respectively, and 1 month later  $58 \text{ ng l}^{-1}$  and  $75 \text{ ng l}^{-1}$  respectively. Samples which have been treated by boiling with acid alone have also shown an increase in measured mercury, to a level which is not as high as that obtained by oxidation.

In samples collected at offshore stations no attempt was made to distinguish between mercury present in solution and that associated with any particulate material present. But, one sample (collected during 1975, in an estuary where pollution does occur and containing a very high suspended load) was filtered through a  $0.22\text{-}\mu\text{m}$  filter membrane; and on analysis  $17 \text{ ng l}^{-1}$  were found in the filtrate and  $950 \text{ ng}$  were found in the particulate associated with that 1-l sample.

Conclusions from these data are that the mercury present in seawater samples is complexed to varying degrees and that a measurement of the total mercury present requires a vigorous oxidation step to make the mercury available for reduction by stannous chloride in cold vapour measurement techniques.

Samples collected in open ocean areas acidified and stored in glass containers are stable for at least 1 month. In samples collected in areas of high suspended load, however, a change in the ratio of 'reactive' to 'total' mercury may occur on storage in acid conditions, although the total mercury is unchanged. In addition a large proportion of mercury present in samples of high suspended load is associated with the particulate matter. The fact that apparently higher levels were found in the Irish Sea than the North Sea may be an artefact of the sampling conditions and proximity to the point of discharge. Those in the western and southern

**Fig. 1** Concentration of reactive mercury ( $\text{ng l}^{-1}$ ) from two surveys in 1976. Values given are mean concentration (range of values) and no. of samples analysed. Positions marked, for example,  $\times 15$  are position of sampling and concentration measured. Where total mercury is also available positions are marked, for example,  $\times 15$  (30).

**Fig. 2** Reactive mercury ( $\text{ng l}^{-1}$ ). Contoured concentration from two surveys (see Fig. 1).  $\bullet$ , positions from January 1976 cruise;  $\times$ , from May-June 1976 cruise.

areas around the UK and the isolated 'high spot' points off the Thames Estuary were collected during a period of extreme storms and consequently high suspended load. The Liverpool Bay samples were collected closer to any point of discharge than, for example, those samples collected off the mouths of the Elbe and Rhine. It may also be significant that in the areas where the levels of mercury are high, sewage sludge is dumped.

The mean and range of values for 'total' mercury concentrations, excluding those individual high spots in the vicinity of discharge points,  $7.9$  ( $3.4\text{--}22$ )  $\text{ng l}^{-1}$ , compare favourably with those obtained by Fitzgerald and Lyons<sup>5</sup> for the North-West Atlantic,  $8$  ( $\pm 3$ )  $\text{ng l}^{-1}$ . Leatherland *et al.*<sup>6</sup>;  $13$  ( $<3\text{--}20$ )  $\text{ng l}^{-1}$ , for the North-East Atlantic; and Burton and Leatherland<sup>7</sup>,  $11\text{--}28$   $\text{ng l}^{-1}$ , for the English Channel. Fitzgerald and Lyons<sup>5</sup> use a method very similar to that described here, but the others use one based on a final colorimetric measurement after concentration by ion exchange.

In contrast, the concentrations measured by Chester *et al.*<sup>8</sup>,  $47$  ( $<0.5\text{--}127$ )  $\text{ng l}^{-1}$  for the world's oceans and by Fitzgerald *et al.*<sup>9</sup>  $140$  ( $\pm 70$ )  $\text{ng l}^{-1}$  for the North-West Atlantic, have much higher means and are much more widely spread. We have not found such high values nor so widely ranged ones, even in areas of obvious contamination.

As with all measurements of heavy metals in seawater samples, great care must be taken to avoid contamination during collection, and loss and/or contamination during storage. Polythene bottles are notoriously contaminated with mercury. It is possible that those investigators who use cold vapour detectors may well be measuring parameters unrelated to the mercury content of the sample. The addition of nitric acid to polythene bottles may cause the release of some organic constituent of the plastic which will absorb at the wavelength used to determine the mercury. Chlorine, produced by oxidising the sample, will certainly interfere with cold vapour detection, and this source of error will have been missed by those investigators who make blank determinations using distilled water in place of 'mercury free' seawater. Despite great efforts to clean it, glassware

**Table 1** Concentrations of total mercury levels where available and ratio of reactive to total mercury for individual areas

Area	Mean total Hg (ng l <sup>-1</sup> ) (range)	Reactive Total
A	6.1 (3.4-9.5)	0.33
B	6.4 (3.9-11)	0.34
C	7.3 (4.3-12)	0.43
D	6.8 (4.8-9.1)	0.31
E	6.6 (3.5-11)	0.50
F	7.5 (5.2-11)	0.41
G	7.9 (5.6-11)	0.39
K	13 (6.0-22)	0.25
L	9.6 (4.8-20)	0.28

used in the oxidation step, will over a very long period, continue to release mercury into the samples, therefore we use quartz vessels during the oxidation step.

Matsunaga *et al.*<sup>10</sup> measured the 'reactive' mercury concentrations in seawater and reported values of 5 (3.6-5.6) ng l<sup>-1</sup> which are in good agreement with the values obtained in this survey, 3.3 (0.9-7.7) ng l<sup>-1</sup>. They did not, however, oxidise their samples and had they done so higher values would have resulted.

The ratios of 'reactive' to 'total' mercury present are similar to those obtained by Fitzgerald and Lyons<sup>1</sup> although the concentrations in this survey were of an order of magnitude lower.

## Mafic and ultramafic rocks associated with granites in the Vardar zone

SEVERAL ophiolitic alignments have been classically recognised in the Dinarides and the Hellenides (Fig. 1). The Eastern alignment, located near the Serbo-Macedonian massif in the Vardar zone, shows curious associations of mafic and ultramafic rocks with granites. Here a brief description of the Guevgueli magmatic complex which belongs to the Eastern alignment helps illustrate this peculiarity: petrographic and major element data seem to prove that these associations occur on the border of opening inter-arc basins.

The Guevgueli complex, in Greek Macedonia, is a large thrust slice within Jurassic sedimentary and volcanic formations<sup>1</sup>. A fault separates this complex into two petrographically distinct units (Fig. 2)<sup>2</sup>. (1) The Western unit is built up of plutonic rocks—gabbroic cumulates, high Fe and Ti diorites (FeO\* 18%; TiO<sub>2</sub> 5%) (FeO\*: total iron as FeO), quartz-diorites and rare trondhjemites—separated from lavas by a continuous layer of hypabyssal formations. All these rocks have a very low K<sub>2</sub>O content and present a tholeiitic differentiation trend<sup>3</sup> with a marked enrichment in FeO\* and TiO<sub>2</sub>.

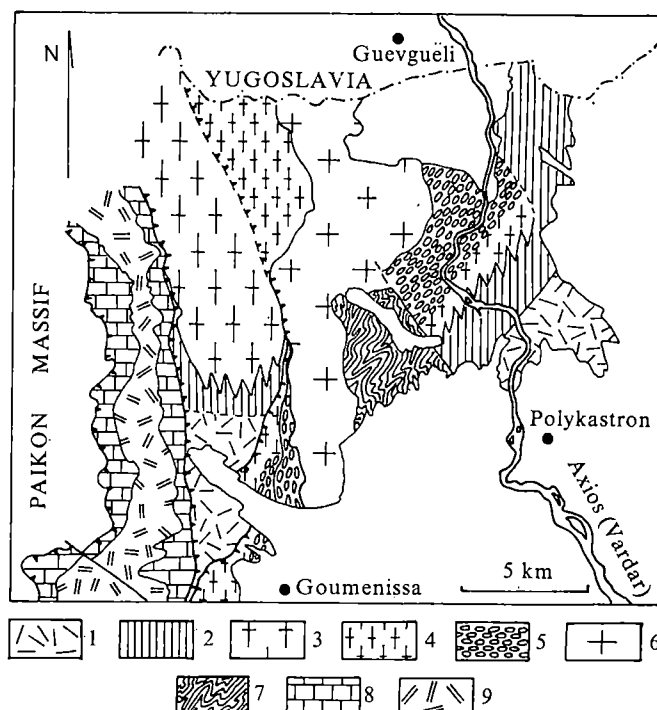

(2) The Eastern unit is more varied: it is made up of lavas, hypabyssal rocks forming a sheeted

**Fig. 1** Structural map of the central part of the Dinarides and the Hellenides. Black areas, ophiolites; stippled area associations of mafic and ultramafic rocks with granites (k, Karadagh; s, Stip; g, Guevgueli).

complex, and gabbroic cumulates cut by abundant magmatic breccias in which dolerites, gabbros, diorites, tonalites, trondhjemites and granites are closely associated. The sheeted complex has a calc-alkaline affinity<sup>3</sup>, whereas the magmatic breccias present a tholeiitic differentiation trend with enrichment in FeO\* and TiO<sub>2</sub>. These rocks are in tectonic contact with biotite-orthoclase-sillimanite-cordierite migmatites. A granite massif (the Fanos Granite) is intrusive into the migmatites, the gabbroic cumulates and the magmatic breccias; the biotites of this granite, dated by K-Ar and Rb-Sr methods, are 150 Myr old (Upper Jurassic)<sup>4</sup>.

The Eastern unit seems to result from the juxtaposition of two groups of magmatic rocks. The first one is made up

**Fig. 2** Geological map of the Guevgueli complex. 1, lavas; 2, hypabyssal rocks; 3, gabbroic formations (Western unit); 4, gabbroic formations (Eastern unit); 5, magmatic breccias; 6, Fanos Granite; 7, migmatites; 8, Mesozoic limestones; 9, volcano-sedimentary formations rich in rhyolites.

of basic, intermediate and acid formations with low  $K_2O/Na_2O$  ratios; the second one consists of granitic rocks with  $K_2O/Na_2O > 1$ . This juxtaposition can be seen in the magmatic breccias, in the sheeted complex which includes microgranitic dykes, and in lavas in which rhyolites are present. These observations lead to the conclusion that the low and high  $K_2O$  formations are contemporaneous.

Ultramafic rocks are scarce in the Greek part of the Guevgueli complex, but they outcrop on the other side of the border in Yugoslavia<sup>5</sup>. Moreover, the Yugoslavian magmatic complexes of Karadagh, near Skopje, and Stip<sup>6,7</sup>,

the  $TiO_2$  content and the  $FeO^*/MgO$  ratio, for low values of  $FeO^*/MgO$ , in abyssal tholeiites; this positive correlation does not appear, or is very weak, in low  $K_2O$  island-arc tholeiites (Fig. 3). The variations of the  $TiO_2$  contents with the  $FeO^*/MgO$  ratio in hypabyssal rocks of the Western unit and magmatic breccias of the Eastern unit of the Guevgueli complex, in dolerites and lavas of the Yugoslavian Karadagh complex, and in abyssal tholeiites are comparable (Fig. 3).

The magmatic complexes of the Eastern ophiolitic alignment in the Dinarides and the Hellenides, therefore, show a

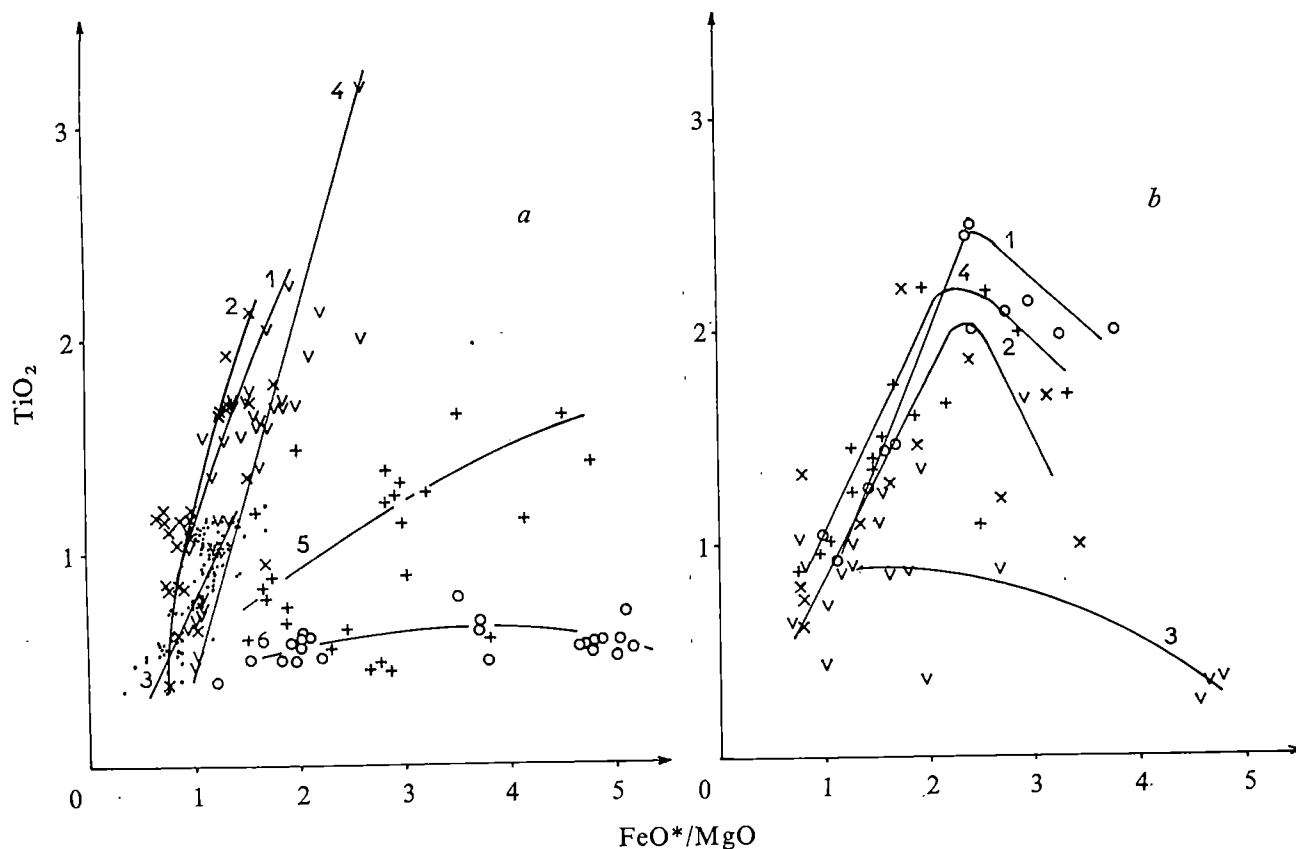

Fig. 3  $TiO_2$ ,  $FeO^*/MgO$  diagrams *a*, of recent volcanic rocks; 1, abyssal tholeiites<sup>8</sup>; 2 ( $\times$ ), basalts from the Lau Basin, an interarc basin between the Tonga and the Lau Ridges<sup>11</sup>; 3 ( $\bullet$ ), basalts from Leg 37 of the Deep Sea Drilling Project (abyssal tholeiites with very low  $TiO_2$  content)<sup>12</sup>; 4 ( $\nabla$ ), basalts from Iceland<sup>13</sup>; 5 ( $+$ ), low  $K_2O$  tholeiites from Hachijo-Jima, Izu-Bonin Arc<sup>14</sup>; 6 ( $\circ$ ): low  $K_2O$  tholeiites from Tonga<sup>15</sup>. *b*, Of magmatic formations of the Eastern ophiolitic alignment in the Dinarides and the Hellenides: 1 ( $\circ$ ), hypabyssal rocks, Western unit, Guevgueli complex; 2 ( $\times$ ), magmatic breccias, Eastern unit, Guevgueli complex; 3 ( $\nabla$ ), hypabyssal rocks, Eastern unit, Guevgueli complex; 4 ( $+$ ), dolerites and lavas, Yugoslavian Karadagh Massif<sup>6</sup>.

located near the Serbo-Macedonian massif, also show close associations of mafic and granitic rocks and include important masses of ultramafic formations (dunites with chromite, lherzolites, harzburgites, pyroxenites).

Thus, all these magmatic complexes exhibit the juxtaposition of distinct associations. The abundance of granites does not seem compatible with an oceanic setting for these rocks. The presence of formations with calc-alkaline affinity (sheeted complex of the Eastern unit) is classically considered to be characteristic of island arcs and active continental margins<sup>8</sup>. Two kinds of magmatic rocks can be compared to the tholeiitic series with low  $K_2O$  content of the Guevgueli complex: low  $K_2O$  island-arc tholeiites and abyssal tholeiites. The similarity between these formations has caused many discussions on the origin of some ophiolitic complexes. It seems that the  $TiO_2$  content can resolve this problem. The low  $K_2O$  tholeiites of island-arcs usually have slightly lower  $TiO_2$  contents than common abyssal tholeiites, but there are many important exceptions<sup>9</sup>. On the other hand, a marked positive correlation can be observed between

close relation in space and time between abyssal tholeiites, island-arc magmatism and granites. Such associations are found on the border of inter-arc basins; so, it seems that the magmatic rocks of the Guevgueli and Karadagh complexes were formed during the creation of inter-arc basins in the Vardar zone. The ultramafic and mafic formations with tholeiitic affinity are relics of the crust and the mantle of inter-arc basins; the calc-alkaline and granitic rocks are the results of the magmatic activity on the borders of these opening basins. This interpretation, if true, is important for our understanding of the structure<sup>10</sup> of the Dinarides and the Hellenides.

## Differences in osmoregulation between wheat genotypes

SEVERAL recent experiments provide evidence to support the existence of osmoregulation in plants as a means of counteracting water stresses induced by changes in the soil or evaporative environment<sup>1-3</sup>. Viewed in terms of energy potentials, decreases in the water potential,  $\Psi$ , induced by changes in the environment, are immediately offset by decreases in the osmotic potential,  $\pi$ , through an increase in solute content. The turgor potential,  $P$ , is thereby maintained since  $\Psi = \pi + P + \tau$  (assuming that the matric potential,  $\tau$ , is small or constant). The importance of this response is that expansion growth, which is affected directly by the turgor potential, is maintained over a range of values of  $\Psi$ <sup>2</sup>. Despite this obvious significance, little is known of the extent of this phenomenon in crop plants in general and in particular of differences between genotypes in the same or closely related species. Here we present evidence indicating substantial differences between several genotypes of wheat; in some osmoregulation was marked, whereas in others it was virtually non-existent.

To examine a wide spectrum of the possible variation, the following genotypes were selected: *Triticum aestivum* spp. *vulgare* (AUS 2067), *T. aestivum* spp. *spelta* (AUS 3843), *T. aestivum* spp. *vulgare* (AUS 3850), *T. durum* (AUS 2816), *T. dicoccum* (AUS 3582) and *T. boeoticum* spp. *aegelopoides* (AUS 90352). After vernalising the plants were grown in pots in a glasshouse with temperatures 20-25 °C during the day and 10-15 °C during the night. Water stresses were produced by withholding water at two stages of development: about 14 d before and 14 d after anthesis. Plants were placed in a controlled environment chamber adjusted to give a flux density of total short wave radiation of 140 W m<sup>-2</sup> at the average plane of the flag leaves and temperatures of 23 °C during the light period

Fig. 1 Relationship of leaf water potential to osmotic potential. The broken line is the line of equality.  $\blacktriangle$ , *T. durum* (AUS 2816);  $\circ$ , *T. aestivum* spp. *vulgare* (AUS 2067);  $\bullet$ , *T. boeoticum* (AUS 90352).

(duration 14 h) and 15 °C during the dark period. Total potential  $\Psi$  was measured on samples of the flag leaves using thermocouple psychrometers and  $\pi$  was measured in the same way after the samples had been frozen in liquid nitrogen<sup>4</sup>. Relative water contents were measured using the technique of Slatyer and Barrs<sup>5</sup>.

When  $\Psi$  falls in response to a reduction in soil water supply, it is usual for  $\pi$  to fall at a slower rate, such that there is a linear decline in the turgor potential until  $\Psi = \pi$ . This pattern has been observed for a range of different plant species, including wheat<sup>6-8</sup>. The response of the genotypes *T. aestivum* spp. *vulgare* (AUS 2067), *T. durum* (AUS 2816), *T. boeoticum* spp. *aegelopoides* (AUS 90352) fit this pattern (Fig. 1). The osmotic potential fell from a value of about -1.5 MPa at full turgor to a value of about -2.5 MPa at zero turgor. This was very similar to the pattern observed in a previous experiment<sup>7</sup>. When osmoregulation occurs we expect  $\pi$  to decrease with  $\Psi$  so as to maintain  $P$ . This was in fact observed for the genotypes *T. aestivum* spp. *vulgare* (AUS 3850), *T. dicoccum* (AUS 3582), and *T. aestivum* spp. *spelta* (AUS 3843) (Fig. 2). Here, over the range of  $\Psi$  for which the leaf had positive turgor,  $\pi$  declined, from an initial value of about -1.5 MPa, at approximately the same rate as  $\Psi$ , thus maintaining  $P$ . At the end of this period of adjustment, when  $\Psi$  had reached about -1.5 MPa and  $\pi$  about -3.0 to -3.5 MPa,  $\pi$  equilibrated rapidly with  $\Psi$ . This phenomenon was observed at both stages of development.

Fig. 2 Relationship of leaf water potential to osmotic potential. The broken line is the line of equality.  $\blacktriangle$ , *T. aestivum* spp. *vulgare* (AUS 3850);  $\circ$ , *T. dicoccum* (AUS 3582);  $\bullet$ , *T. aestivum* spp. *spelta* (AUS 3843).

If the solute content of the leaves did not vary with the relative water content,  $\zeta$ , then  $\pi$  should be altered by gains or losses of water according to the equation<sup>9</sup>

$$\pi = (\pi_t \zeta_t) / \zeta \quad (1)$$

or if bound water is present,  $(\pi + \tau) = (\pi_t + \tau_t) \{ (1 - B) / (\zeta - B) \}$  where  $B$  is the amount of  $\zeta$  that is bound, and the subscript  $t$  indicates the value at full turgor. If the response is described by equation (1), then the relationship between  $\log \pi$  and  $\log \zeta$  will be linear. This was in fact so for the genotypes showing no evidence of osmoregulation, an example being *T. durum* (Fig. 3a). A value of  $\pi_t$  of -1.3 mPa was found by fitting a regression line to the data and then using this value in equation (1). The line predicted by this equation was reasonably close to the fitted line (Fig. 3a).

For genotypes showing evidence of osmoregulation, the

Fig. 3 Changes in the relative water content with osmotic potential for a, *T. durum* (AUS 2816) and b, *T. aestivum* (AUS 3850). The broken line is the line of best fit, the intact line that predicted by equation (1) and the dotted line an interpretation of Fig. 3b.

relationship seemed to consist of two distinct linear phases, as shown for *T. aestivum* (AUS 3850) in Fig. 3b. In the first, which covered the range of  $\pi$  from  $-1.5$  to  $-3.0$  MPa, there was virtually no change in  $\zeta$ . Since changes in  $\pi$  balanced changes in  $\Psi$  over this range (Fig. 2), the relative water content was conserved for changes in  $\Psi$  as well. At the end of this phase, there was a linear decline in  $\pi$  similar to that observed for plants of the type shown in Fig. 3a.

This pattern, being bi-modal, cannot be described by equation (1). Also, it is difficult to explain in terms of so called bound water, since the level would have to be about 0.9 in order to explain the first phase, with a rapid change to almost zero in order to explain the second. This would presumably require a sudden decrease in the amount of colloidal material in the leaf tissue. A more plausible explanation may be found if we assume that the solute content changes with decreases in  $\Psi$  up to the end of the first phase, that is, that osmoregulation occurs. At the end of this phase it seems that this process ceases and that  $\pi$  then declines with change in  $\Psi$  due to loss of water from the tissue and subsequent increase in the solute concentration, that is, according to equation (1). It is not clear from these results what limits solute accumulation, or why it should be present in some genotypes and not others. Indeed, there seems little point in speculating on these issues until more information has been obtained. It is, however, clear that the two types of response can occur in wheat, and that when osmoregulation occurs the turgor potential can be maintained over a substantial range of  $\Psi$ —up to  $-1.5$  MPa. More importantly, these results suggest that large genotypic variations in osmoregulation may exist, and that it may therefore be possible to improve the drought hardness of commercial wheat varieties by breeding for this characteristic.

## Changes in release rates of cyanide in relation to palatability of *Sorghum* to insects

*SORGHUM* leaves contain the cyanoglycoside dhurrin located in the cell vacuole<sup>1</sup>, and when the tissue is crushed, hydrolysis of dhurrin by an enzyme system probably present in the cytoplasm<sup>1</sup> results in the release of HCN. Cyanogenesis is probably a mechanism to protect plants from being eaten by herbivores<sup>2,3</sup>. It is generally assumed that this protection is conferred by the toxic effects of cyanide but the mechanism has not been fully investigated and the cyanoglycosides themselves or the other end products of hydrolysis may deter feeding. The degree of liberation of HCN in leaves is dependent on the age and variety of plant, as well as on certain environmental factors<sup>4–7</sup>. Leaves of young *Sorghum* are often rejected at the first bite by the graminivorous locust, *Locusta migratoria*<sup>8</sup> but older *Sorghum* is eaten in large quantity. We show here that change in palatability is related to the rate at which HCN is released from the leaf at the time of biting.

Crystals of dhurrin (*p*-hydroxymandelonitrile- $\beta$ -D-glucoside) (melting point  $164^{\circ}$ – $168^{\circ}$  C), which liberated HCN when emulsin was added, were extracted<sup>9</sup> from 8-d-old *Sorghum bicolor* (variety 65D, from Botswana) grown in controlled conditions (18 h light,  $25^{\circ}$  C day,  $20^{\circ}$  C night). When dhurrin was tested for palatability by *Locusta* nymphs, by absorbing it on to sucrose-impregnated glass fibre papers which *Locusta* normally eat, it had no effect on feeding. The hydrolysis of dhurrin is stoichiometric<sup>10</sup> yielding, in addition to HCN, *p*-hydroxybenzaldehyde: this also had no effect on feeding. During the hydrolysis of dhurrin in freeze-dried *Sorghum* leaves, *p*-hydroxybenzaldehyde at first built up and then began to disappear from the test solution (compare ref. 10): the absorption maximum (in alkaline solution) shifted from 330 nm (*p*-hydroxybenzaldehyde) to 285 nm as the reaction proceeded probably because of accumulation of chelidonic acid<sup>11</sup>. Attempts to determine any antifeedant activity have proved inconclusive.

The release of HCN from crushed leaves was measured quantitatively by monitoring production of *p*-hydroxybenzaldehyde (Fig. 1). The amount released was very high in young plants and declined with age. On very young *Sorghum* insects

Fig. 1 Formation of *p*-hydroxybenzaldehyde from dhurrin present in *Sorghum* at different stages of development. Fresh tissue (0.5 g) of *Sorghum* 65D aged 8 d, 11.5 cm (●), 15 d, 16 cm (○), 30 d, 24 cm (▲) and 53 d, 40 cm (△) was crushed in distilled water (50 ml) and the mixture was aerated. Samples (5 ml) were withdrawn after 5 min and at 15-min intervals for 2 h, the reaction was stopped by the addition of acid and *p*-hydroxybenzaldehyde was extracted into ether, then into sodium bicarbonate and re-extracted into ether after acidification. The extracts were concentrated to dryness, the residue was redissolved in methanol and the absorbance at 285 nm due to *p*-hydroxybenzaldehyde was recorded.

Fig. 2 Release of HCN from *Sorghum* at different stages of development in relation to feeding by *Locusta migratoria migratorioides*. Initial rates of release of HCN from *Sorghum* (●), as would occur on biting, could be calculated from data in Fig. 1 because the hydrolysis of dhurrin yields 1 mol of HCN and 1 mol of *p*-hydroxybenzaldehyde. Percentage inhibition of feeding (○) was found by comparing meal sizes of 5th instar nymphs on *Sorghum* of different ages, with meal sizes on mature, palatable leaves of *Poa annua* used as a control. (Standard deviations are indicated by vertical lines.)

reject the plant quickly; if HCN is the important deterrent it will be the amount released immediately on biting that is relevant rather than the capacity of the plant to produce HCN over a long period. The initial rate of HCN release was calculated for each plant age, and its relationship to the amount eaten in one meal is shown in Fig. 2.

The possibility of a rapid response to HCN was confirmed by introducing hydrocyanic acid into the mouth region of *Locusta*, by means of a previously fitted cannula, when the insect was feeding on a palatable grass. Concentrations as low as 0.01 mM were sufficient to inhibit feeding (Table 1). The amount of HCN initially released from young *Sorghum* (8-d-old) was calculated to be equivalent in concentration to a solution of between 0.5 mM and 1.0 mM hydrocyanic acid and thus would be effective as a deterrent.

Cyanoglycosides have been shown to have no effect on feeding by insects, nor to stimulate feeding at concentrations which occur naturally<sup>12</sup>. On the other hand, the release of HCN has been shown to protect bracken (*Pteridium aquilinum*)<sup>13</sup> and cassava (*Manihot esculenta*)<sup>14</sup> from insect attack. We have shown that *Sorghum* plants are best protected from insect attack when very young, and this protection is conferred by the HCN release on biting rather than by the cyanoglycoside itself or other products of its hydrolysis. Our work emphasises also

Table 1 Tests with hydrocyanic acid solution

Approx. concentration of HCN solution	No. of insects tested	Behaviour of 5th instar <i>Locusta</i> nymphs		
		No response	Feeding stops, but no backward movement	Feeding stops, also backward movement
1.0 M	5	0	0	5
0.1 M	5	0	0	5
0.01 M	10	0	4	6
1.0 mM	10	1	7	2
0.1 mM	10	4	6	0
0.01 mM	10	6	4	0
Water	10	10	0	0
Air	20	20	0	0

Different concentrations of hydrocyanic acid were introduced into the cibarial cavity of 5th instar nymphs through a chronically implanted cannula. Each insect had been deprived of food overnight and was tested during feeding on a palatable blade of grass. All tests were done during the first 3-min of feeding.

the importance of the initial rate of release of HCN when the insect bites.

We thank the Director and Dr Keith Jones of the Royal Botanic Gardens, Kew for facilities.

## New approach to pollen culture

RESEARCH on pollen and anther culture is important for genetic and mutation studies, and has many potential applications in plant breeding and crop improvement. In our experience, the technique of pollen culture developed by Nitsch and co-workers<sup>1,2</sup>, though successful with a wide range of species<sup>3</sup>, is much more difficult than anther culture and involves procedures which are unreliable and inefficient. Furthermore, plant yields are generally lower than when anther culture is used. We describe here an alternative approach which retains the simplicity and reliability of anther culture while eliminating the need for either mechanical disruption<sup>1,2</sup> or surgical manipulation<sup>4</sup> of anthers.

Our approach exploits the fact that, in many species, anthers dehiscence soon after inoculation, and if they are floated on shallow layers of liquid medium in plastic Petri dishes, pollen is 'shed' into the medium. This shed pollen will continue to grow if the anthers are removed from the dishes. Shedding continues throughout the culture period; hence, by frequent transfer of anthers to fresh medium a sequence of pollen cultures can be obtained from the same batch of anthers.

Examples of cultures of pollen shed from anthers, instead of mechanically isolated from them, are shown in Fig. 1 for *Nicotiana tabacum*. Illustrated is a series of cultures initiated with anthers of increasing age (Fig. 1 a-d) and in which the anthers have been transferred into fresh medium at 6, 10 and 14 d; in each case dishes were resealed after transfer of the anthers and reincubated together with a fourth dish containing the residual anthers (R). In cultures initiated at the unicellular pollen stage (microspores) (Fig. 1a), anthers do not open to any great extent and little shed pollen develops over the first 14 d. With increase in anther age, however, the time to anther opening decreases whereas embryo yields increase, and shed fractions develop at progressively earlier stages of culture (Fig. 1b, c). With anthers containing wholly young bicellular pollen grains (microgametophytes) (Fig. 1c), shed fractions develop after 0-6 d. Pollen is shed most rapidly in cultures of still older anthers (Fig. 1d) but as is now well known the embryogenic potential of older anthers is limited.

Chilling of buds before excision and culture of the anthers<sup>1</sup> is another important requirement for early dehiscence of tobacco anthers. We find periods of 12 d and longer at 7-8 °C optimal for this species. To minimise water loss during cold treatment, we store the buds in polythene bags wrapped in thin aluminium foil, a procedure which also maintains a high percentage of viable pollen (as assessed by fluorescein diacetate<sup>5</sup>). Illumination of cultures for the whole of the culture period has

**Fig. 1** *Nicotiana tabacum* cv. White Burley. Effect of developmental stage on anther dehiscence and liberation of pollen into liquid culture medium. *a*, Unicellular pollen stage (corolla length 13–15 mm). *b*, First pollen division stage (17–19 mm). *c*, Early bicellular pollen stage (21–23 mm). *d*, Bicellular stage just before deposition of starch (28–30 mm). In all cases, buds were stored at 7–8 °C for 12 d before excision and inoculation of the anthers. At inoculation, 12 anthers from three buds of similar stage were floated on the surface of 5 ml of liquid A medium. They were transferred to fresh A medium after 6, 10 and 14 d. All dishes were sealed with Parafilm and incubated at 28 °C in darkness for the first 14 d. After 14 d, they were transferred to light (Grolux tubes, 12-h day, 500 lx) at 25 °C. Embryo counts were made under a binocular after 35 d while the embryos were still small and separate from each other. Chromosome counts made on 10 embryos from each dish in (*b*) and (*c*) were all haploid. R, dish containing the residual anthers. A medium, major salts (half strength) and Fe-EDTA (full strength) of Murashige and Skoog<sup>10</sup> plus sucrose 2%; pH 5.5.

so far proved detrimental as has shaking them on a horizontal shaker at 130 r.p.m. Our best results have been obtained with stationary cultures incubated in darkness for 14 d at 28 °C before transfer to light at 25 °C.

The performance of tobacco pollen 'shed' from anthers initially at the mitotic to early bicellular stages and that of pollen mechanically isolated from the anthers is indicated by the data of Table 1. Embryo yields are given for fractions shed into a simple nutrient medium (A medium) and fractions of isolated pollen mounted in either A medium or A medium supplemented with glutamine, serine and *myo*-inositol (AGSI

medium) as recommended by Nitsch<sup>2</sup>. If we consider the data for the 8-d chilled material (which show the highest yields), it will be seen that the isolated pollen responds to AGSI medium (but not A medium) after preculture of the anthers for 3 d or longer, thus confirming Nitsch's findings. But in none of the pollen isolates is the yield as great as in the anther-culture controls. Shed fractions start to develop in the 8-d chilled material after 7 d of culture and by 9 d the yield exceeds that in any of the isolated fractions. The pollen is shed into A medium and the fact that it will then grow in the absence of the anther tissues implies a conditioning of the medium by the

**Table 1** Comparison of embryo yields in cultures of anthers, isolated pollen and shed pollen of *Nicotiana tabacum* cv. White Burley

Pollen fraction	Time of chill (d)	Preculture before isolation of pollen (d)										No isolation anther-culture controls	
		1		3		5		7		9		35	
Isolated	0	I	II	I	II	I	II	I	II	I	II	I	II
	4	0	0	0	0	0	0	0	3	1	5	22	35
	8	0	0	0	3	0	9	0	0	0	30	37	68

	4	0	0	0	0	0	0	0	0	1	8		
	8	0	0	0	0	0	0	34	90				

Mean embryo yields per anther from two experiments. I, Pollen cultured in A medium (see Fig. 1). II, Pollen cultured in AGSI medium (A medium plus L-glutamine 800 mg<sup>-1</sup>, L-serine 100 mg<sup>-1</sup> and myo-inositol 5,000 mg<sup>-1</sup>). In each experiment, three groups of 25 buds were harvested at the mitotic to early bicellular pollen stage (corolla length 17–23 mm). One group was dissected without cold treatment, the other two groups were stored at 7–8 °C for 4 and 8 d respectively before dissection. After dissection the five anthers from each bud were distributed singly into 5-cm Petri dishes containing 5 ml of liquid A medium, to give five replicates each of 25 anthers. One anther was then removed from each dish and floated on 5 ml of A medium, and a second anther from each dish was floated on AGSI medium (anther-culture controls). At 1, 3, 5, 7 and 9 d, one dish was taken from each group of five. Dead anthers (dark brown) were rejected; the remainder (about 20) were then removed and the dish resealed ('shed' fraction). The anthers removed were gently ground in a Potter glass homogeniser. Homogenates were filtered through 100-µm nylon and the filtrate centrifuged for 4 min at 100g. The supernatant was discarded. The pellet was resuspended in 10 ml of A medium, divided into two aliquots, recentrifuged and the supernatants again discarded. One pellet was inoculated into 5 ml A medium, the other into 5 ml of AGSI medium (isolated pollen). All dishes were sealed with Parafilm and incubated at 28 °C in darkness for the first 14 d, thereafter at 25 °C in Grolux light (12-h day, 500 lx). Embryos counted after 35 d. All buds were harvested within 2 weeks from the same batch of glasshouse plants grown through November to January under supplementary illumination.

anther tissues. Tapetum has long been thought to have a nutritive function and it is thus possible that conditioning of the medium stems from materials released from degenerating tapetal cells. Conditioning is a continuous process, and it is evident from the serial cultures of Fig. 1 that contact between anthers and medium for as little as 4 d is sufficient to support growth of large numbers of embryos. Evidence of medium-conditioning by anther tissues has also come from work on pollen isolated by surgical manipulation of anthers<sup>4</sup>.

In its simplicity the new approach to pollen culture has decided advantages for both applied and fundamental research. For mutation studies, we see no intrinsic objection to the use of fractions shed after between 0 and 6 d instead of fractions mechanically isolated from anthers at, say, 3–4 d. Besides eliminating possible deleterious effects of the homogenised anther tissues, the new procedure leaves the tissues intact, making them available for further experimentation and analysis. The new procedure is particularly attractive to large-scale manipulation of species possessing minute anthers, as in some of the cereals, and we have already found that, in barley, pollen calluses emerging from floating anthers are shed into the medium. Encouraging results have also been obtained in other Solanaceous species. Scrupulous attention must be given to anther-staging. For instance, in *N. knightiana*, anthers in the immediate post-first-division stage of the pollen are crucial, whereas in *Hyoscyamus niger*, the immediate pre-division stage seems to be the most productive. The success of the new procedure is undoubtedly due to the use of liquid, instead of agar, media. Advantages of liquid media, first reported for *N. tabacum* by M. Devreux (at the 1974 Haploid Conference held in Guelph), are now being realised by other workers and exploited in different species<sup>6–9</sup>.

## Reproductive roles in the simultaneous hermaphrodite *Aplysia dactylomela*

THE opisthobranch gastropod *Aplysia* is a simultaneous hermaphrodite with internal fertilisation. The functional morphology of the reproductive system<sup>1–4</sup> has been well studied and oviposition is known to be under some hormonal control<sup>5–7</sup>. Adults may assume the role of sperm donor or recipient, or both at the same time. Recent discussions of the evolutionary significance of simultaneous hermaphroditism<sup>2,8–14</sup> as well as considerations of the relative roles of sperm donors and recipients in selecting partners<sup>15,16</sup>, have suggested that *Aplysia* offers an opportunity to investigate the processes involved in the assumption of different sex roles in the same animal. Accordingly we analysed data collected several years ago during other field studies of *Aplysia dactylomela*<sup>17,18</sup>. We found that most animals were as likely to be sperm donors as recipients during different copulations, and there was a significant relationship between frequency of copulation and number of different partners in the total population studied. A few individuals, however, were found to copulate with fewer partners than sperm recipients.

We used *A. dactylomela* maintained in the Lerner Marine Laboratory, Bimini, Bahamas. Animals were collected during the day from the thalassia flats of the Bimini lagoon and placed in 1,000-l concrete tanks supplied with water from the ocean. The behaviour of groups of 5–10 animals was observed every 30 min between 0530 and 1130 and between 1200 and 2300 for 3 weeks; each group was observed 3–22 times. Individuals were identified by a colour-coded stainless steel safety pin inserted through the parapodium. Time of day had been shown to influence the probability that the animals would be found alone or copulating in their natural habitat<sup>18</sup>; we found that the same was true of animals maintained in laboratory conditions. Copulations occurred significantly more often in the morning ( $P < 0.05$ ,  $\chi^2$  test<sup>19</sup>). We also confirmed that time of day did not significantly relate to the number of times animals were found alone, or in contact.

As Fig. 1 shows, most individuals were observed copulating

between three and seven times. To facilitate statistical analysis of the roles assumed in copulation, we selected animals which copulated five times or more. This enabled us to use the binomial test with an associated probability of 0.06 or less<sup>19</sup>. By this criterion, we had 26 individuals which copulated five or more times. Of these, 17 did not copulate consistently in one or the other role, four were sperm recipients more often than donors, and five were sperm donors more often than recipients.

Thus our sample behaved as might be expected of simultaneous hermaphrodites in that the probability of finding individuals which consistently assumed one or another sexual role was relatively low. But we wanted to know whether the nine consistent animals represented a true behavioural subsample. It seemed that the three behavioural 'types' might be distributed differentially with respect to frequency of copulation.

As Fig. 2 shows, the number of times an individual copulated was positively correlated with the number of different partners ( $r_s = 0.86$ ,  $P < 0.01$ ). Animals which consistently assumed the same sex role were in a different part of the distribution from the others. The group medians for number of different partners (3.5) and number of observed copulations (5.5) segregated seven of these nine animals in the upper right quadrant of the graph. Thus all the consistent sperm recipients and three of the five consistent sperm donors copulated frequently and with many different partners. Further comparisons suggested that sperm recipients copulate with more partners than do sperm donors (Mann-Whitney  $U$  test,  $U = 3$ ,  $P = 0.056$ ).

This latter finding implies some degree of interindividual organisation that may be significant for adaptations of the species. We cannot eliminate the possibility that the differences in donor or recipient roles are due to sampling error; although individuals were collected at the same time, they may have been at different developmental stages or in different reproductive states. But if some part of any population behaves consistently as donors or recipients for a significant time, selection could act on them when pressures favour or disfavour behaviourally dimorphic individuals in reproduction.

We saw egg-laying animals simultaneously acting as sperm recipients but not as sperm donors. Genetic variability might therefore be increased in the least 'expensive' way if the sperm donor spends energy searching for sperm recipients, while the recipient spends energy on oviposition. Even though the whole population 'spends' equally on female and male functions, the differential behaviour patterns of a small group of individuals may well be significant for selection processes<sup>9,20</sup>. Thompson and Bebbington<sup>4</sup> suggested that *Aplysia* sperm are activated only after transfer to the recipient. Further work is needed to determine which sperm are more likely to fertilise the eggs—the more recently donated sperm, or that from previous copulations which has been stored for some time. Competition between sperm, such as that described for insects<sup>21</sup>, may be a mechanism in *Aplysia* by which more successful reproductive behaviours are selected.

Charnov and Bull<sup>11</sup> argued that in sessile simultaneous hermaphrodites selection favours the ability to alter the ratio

Fig. 1 Copulation frequencies observed in 37 individual *Aplysia dactylomela* maintained in tanks in the Lerner Marine Laboratory.

Fig. 2 Relationship between frequency of observed copulation and number of partners in *A. dactylomela*. ♀, sperm recipient; ♂, sperm donor; ●, one animal.

of sperm to ova in response to changing environmental conditions. It is possible that in the highly mobile *Aplysia*, the quantity and function of stored sperm may be regulated by the organisation of copulatory interactions.

## Gametogenesis in culture by gametocytes of *Plasmodium falciparum*

CONTINUOUS culture of human malaria parasites, *Plasmodium falciparum*, in human red blood cells was first reported by Trager and Jensen<sup>1</sup> and subsequently by Haynes and co-workers<sup>2</sup>. The culture system described by Trager and Jensen supports the asexual multiplication of *P. falciparum* and the formation of gametocytes (the precursors of the gametes). Gamete formation by cultured *P. falciparum*, without which the parasites are unable to infect mosquitoes, has not been previously described. We report here that gametocytes of *P. falciparum* grown from parasites maintained by continuous culture *in vitro* are able to develop to the point at which they can be stimulated to undergo gametogenesis (exflagellation).

The isolate of *P. falciparum* used in this study was adapted to culture on 4 January 1977 from the blood of an individual who had become infected during a visit to Zaire from September to December 1976. This isolate, designated the Z strain, was obtained with the kind cooperation of Dr David Wyler. The parasites were adapted to growth in red cells of blood type A. Infected cells were suspended in culture medium at a haematocrit of 6%, placed in 30 ml tissue culture flasks (Corning no. 25100) with a 25 cm<sup>2</sup> culture surface area and incubated at 37 °C. Each flask contained 5.0 ml of cell culture. The medium used in routine culture was that described by Trager and Jensen<sup>1</sup> and consisted of RPMI 1640 powdered medium supplemented with HEPES buffer (25 mM) and 0.2% NaHCO<sub>3</sub> with 10% human serum type AB. Each day the culture medium was removed from the surface of the settled cells and replaced with fresh medium. Flasks were gassed with a mixture containing 6% O<sub>2</sub>, 3% CO<sub>2</sub> and 91% N<sub>2</sub>. During routine maintenance the parasite cultures were diluted with fresh red cells every 4–8 d. Parasite densities usually rose to between 1% and 2% of blood cells infected.

Smalley<sup>3</sup> has reported that gametocytes in non-growing

cultures of *P. falciparum* require 10 d to develop from a merozoite to a stage approaching morphological maturity. In the present study certain cultures were maintained for 2–3 weeks without dilution to allow gametocytes to reach full maturity. In cultures maintained in this way immature gametocytes were usually present after 1 week. By 2 weeks numerous gametocytes were usually present including many with the morphological appearance of maturity (Fig. 1).

In one culture vessel, set up on 25 February 1977 when the parasites had been maintained in continuous culture for almost 7 weeks, the regular medium was replaced 15 d later with one containing 50% serum instead of the usual 10%. The culture was maintained in this medium thereafter. Eight days after substituting with the new medium the gametocytes density was 0.6%. At this stage almost 50% of the gametocytes were apparently mature by morphological criteria on blood smears stained with Giesma's stain. Mature gametocytes of both sexes were crescent shaped cells with rounded ends and pigment granules concentrated near or over the nucleus near the centre of the crescent (Fig. 1). Male and female gametocytes were distinguished from one another by their staining properties. The cytoplasm of female gametocytes stained blue while that of males stained orange-pink and was not easily distinguished from the nucleus. About 35% of all gametocytes were morphologically mature females and about 10% were morphologically mature males. The remaining gametocytes were in various stages of development.

Gametocytes from this culture were stimulated to undergo gametogenesis by the following method. On the eighth day after substituting with medium containing 50% serum the cells were evenly resuspended in their own culture medium and 0.3 ml of the suspension dispensed in a serum tube into 3.0 ml of foetal bovine serum (FBS) adjusted to pH 8 with 1.5% NaHCO<sub>3</sub>. The cells were sedimented by centrifugation for 30 s; most of the supernatant was removed and the packed cells were resuspended in a minimum volume of the remaining supernatant fluid. One drop of this cell suspension was placed on a microscope slide, a cover slip placed on top and the preparation examined

**Fig. 1** Gametocytes and gametogenesis of *P. falciparum* in culture. *a*, Morphologically mature macrogametocyte; *b*, morphologically mature microgametocyte; *c*, macrogamete 25 min after initiation of gametogenesis; *d*, *e*, *f*, exflagellating microgametocytes showing the release of microgametes 25 min after initiating gametogenesis. All preparations were methanol fixed and stained with Giesma's stain.

under a microscope. Between 5 and 10 min after the cells had been resuspended in FBS extensive rounding of gametocytes was observed. At 15 min the first exflagellation was seen (Fig. 1). During subsequent observation, up to 45 min, about one exflagellating male gametocyte was observed per 10,000 red blood cells. This represents about one exflagellating male gametocyte for every five male gametocytes judged to be mature by morphological criteria. Over 50% of female gametocytes judged morphologically mature were found to have rounded up to form female gametocytes when examined on blood smears stained with Giesma's stain.

When gametocytes were examined on a slide in culture medium without washing in FBS at pH 8.2, no evidence of gametogenesis was seen during 45 min of observation under the microscope.

Two days later the experiment was repeated on the same culture using human serum adjusted to pH 8.2 instead of FBS as the exflagellating medium. Gametogenesis (exflagellation) was again successfully initiated. The same method for stimulating exflagellation was applied to three other cultures. These were only 2 weeks old and had been maintained throughout in medium containing 10% human serum. In two of these cultures exflagellation was successfully initiated although the frequency of exflagellation events was less than that observed in the 3-week-old culture.

It is clear from these results that gametocytes produced by the Trager-Jensen system of malaria cultures can develop to a point at which they are capable of undergoing gametogenesis. At this stage our observations are not adequate to define the precise conditions required to achieve this reproducibly. Prolonged maintenance of cultures for at least 2 weeks is probably important to allow gametocytes to reach full maturity. Transfer to a medium containing high serum may also be important in this respect. It is well known that certain malaria parasites (for example, rodent malaras) lose their ability to form gametocytes after prolonged blood passage in laboratory hosts without mosquito transmission. An analogous situation may apply to *P. falciparum* maintained for prolonged periods in culture. If this is true it may be significant that we achieved our results with a line of parasites recently isolated from a natural infection.

Account should also be taken of the fact that the demonstration of exflagellation *in vitro* depends on the use of appropriate methods for stimulating gametogenesis. In studies with other species of malaria parasites it has been found that bicarbonate-containing media at pH 8.0, most effectively animal sera, are excellent for this purpose<sup>4,5</sup>. At pH values below 7.7 and in media from which bicarbonate is absent exflagellation usually does not take place. In the conditions used to culture *P. falciparum* the Trager-Jensen culture medium is maintained at a pH of 7.3 to 7.4. The presence of a powerful buffer (25 mM HEPES) in this medium may prevent the pH from rising sufficiently rapidly to initiate gametogenesis during equilibration with the atmosphere. Thus after exposing a drop of the cell suspension to the atmosphere, the method commonly used to initiate exflagellation, we were unable to observe gametogenesis by gametocytes in their original culture medium. By washing and resuspending cultured gametocytes in bicarbonate supplemented sera at pH 8.0, exflagellation was readily demonstrated.

Our observations demonstrate that cultured blood stages of *P. falciparum* are capable of generating gametocytes able to undergo gametogenesis. Although the conditions which would enable this to be carried out on a regular basis are not completely defined there is good reason to expect that cultured blood stages of *P. falciparum* may be used to generate the gametes and mosquito stages of this parasite.

We thank Drs William Trager and James B. Jensen for

introducing us to the methods for culturing *P. falciparum* and Drs Mary M. Nijhout and J. David Haynes for their encouragement and assistance.

## 'Strong' phase response curve for the circadian rhythm of locomotor activity in a cockroach (*Nauphoeta cinerea*)

ANALYSIS of entrainment in circadian systems depends on a knowledge of the phase resetting effects of the light (or temperature) pulses perturbing the circadian oscillation. Thus when a light pulse of a particular intensity and/or duration falls at certain phases of the free-running oscillation it may generate phase-advances ( $+\Delta\phi$ ) in subsequent activity; when it falls at other phases it may generate phase-delays ( $-\Delta\phi$ ). A plot of such phase changes, both magnitude and sign, as a function of the phase of the oscillation so perturbed, is called a phase response curve (PRC) (refs 1, 2). In a systematic study of the resetting effects of light pulses on the rhythm of pupal eclosion in *Drosophila pseudoobscura*, Winfree<sup>3</sup> demonstrated two topologically different types of PRC, depending on the strength of the signal. When light pulses were 'weak' ( $< 50$  s blue light,  $10 \mu\text{W cm}^{-2}$ ) phase shifts were small. When pulses were 'strong' ( $> 50$  s) phase shifts became abruptly larger, up to 10-12 h. Because of the way Winfree's data were graphically presented, weak resetting curves were called type 1 and strong curves type 0. An abrupt change from type 1 to type 0 has been observed only in circadian systems which control physiological events such as pupal eclosion (refs 1-3 and D.S. in preparation) and oviposition<sup>5</sup> in populations of insects. Rhythms of locomotor activity in single animals, on the other hand, have only shown low amplitude type 1 curves<sup>6,7</sup>. Entrainment in 'physiological' rhythms is in most cases mediated by extraoptic photoreceptors and a hormonal output<sup>8</sup>. 'Behavioural' rhythms, on the other hand, most frequently involve entrainment by way of the organised photoreceptors<sup>9,10</sup> and an electrical (neural) output<sup>10-12</sup>. Truman used these differences to distinguish two types of biological clock<sup>13</sup>. Here, however, we report PRCs which switch from type 1 to type 0 in the locomotor activity rhythm of a cockroach *Nauphoeta cinerea*, which might from earlier literature have been expected to show only type 1 resetting.

Newly-emerged males of *N. cinerea* were housed singly in small Perspex running wheels, in light-tight boxes at  $25 \pm 0.5^\circ\text{C}$ . Each revolution of the running wheel caused four closures of a magnetic proximity switch, and the activity of the cockroach was thus recorded by an Esterline-Angus event recorder. For each insect, activity records for successive 24-h periods were pasted down in chronological order on poster boards (Fig. 1). Records of locomotor activity were then photographed and 'double-plotted' to enhance any rhythmic features.

Insects were initially entrained to a light cycle of 12 h of light and 12 h dark (LD 12:12) for 10-14 d. The lights were then turned off and the activity rhythms allowed to free-run in continuous darkness. Measurements of free-running periods ( $\tau$ ) were made by eye-fitting a line to the onsets of activity (Fig. 1), the slope of the line indicating  $\tau$ . Cockroaches in free-running conditions were then perturbed by single 3 h or 12 h light pulses ( $240 \mu\text{W cm}^{-2}$ ), with

**Fig. 1** Locomotor activity rhythms of two males of the cockroach *Nauphoeta cinerea*. *a*, 'Free-running' in continuous darkness (DD) and perturbed by single 3-h pulses of white light ( $240 \mu\text{W cm}^{-2}$ ) at: 1, circadian time (Ct) 14.7 ( $-\Delta\phi 2.5 \text{ h}$ ); 2, Ct 17.1 ( $+\Delta\phi 0.5 \text{ h}$ ); 3, Ct 13.3 ( $-\Delta\phi 3.1 \text{ h}$ ). *b*, Initially entrained to LD 12:12, then: 1, 'free-running' in DD and perturbed by single 12-h pulses of white light ( $240 \mu\text{W cm}^{-2}$ ) at: 2, Ct 10.2 ( $-\Delta\phi 9.8 \text{ h}$ ); 3, Ct 13.5 ( $+\Delta\phi 11.8 \text{ h}$ ); 4, Ct 22.3 ( $+\Delta\phi 2.2 \text{ h}$ ); 5, Ct 15.9 ( $+\Delta\phi 7.0 \text{ h}$ ). Activity records are 'double-plotted' to enhance rhythmic features. Light treatments are shown as open boxes in the left-hand panel.  $-\Delta\phi$ , delay phase shift (h);  $+\Delta\phi$ , advance phase shift (h).

**Fig. 2** Phase response curves for 3-h (a) and 12-h (b) pulses of white light ( $240 \mu\text{W cm}^{-2}$ ) in the cockroach *Nauphoeta cinerea*. For 3-h pulses the response curve is of the 'weak' type 1 with small phase changes (4–5 h). For 12-h pulses the response curve is of the 'strong' type 0, drawn either as a 'saw-tooth' curve showing phase delays and phase advances (up to 12 h), or as a monotonic straight line with all phase changes plotted as delays ( $y = -1.06572x + 1.6640$ ;  $r = 0.96$ ;  $P < 0.001$ ).

the resetting pulses being timed to occur at all phases (circadian times, Ct) of the insects' endogenous circadian period. Phase shifts, in hours, were measured as displacements in activity onsets before and after the pulse.

The phase response curve for 3-h pulses of white light ( $240 \mu\text{W cm}^{-2}$ ) (Fig. 2a) was of the low 'amplitude' type 1 with phase delays early in the 'subjective night' (Ct 12–18) and phase advances late in the 'subjective night' (Ct 18–24). Maximum phase changes were in the order of 4–5 h. Phase advances were distinguished from phase delays, not only by their final steady state in relation to the activity onset before the pulse, but also on the criterion of reaching that steady state through a series of non-steady-state or transient cycles, which are evident for advances but not delays<sup>1</sup>. For 12-h pulses phase changes were much larger, the resultant response curve (Fig. 2b) either being represented by a high amplitude saw-tooth with a  $360^\circ$  'dataless' change of phase between delays and advances at about Ct 13 or, more realistically perhaps, by its linear or monotonic form, treating all phase changes as delays. In this connection all phase changes except one (that starting at Ct 2.9) were devoid of transients.

Earlier results with cockroaches (*Leucophaea maderae*) showed only small phase shifts even with light pulses of  $2,000 \text{ lx}$  (about  $800 \mu\text{W cm}^{-2}$ ) and 12 h duration<sup>14</sup>. But other results for the same species<sup>15</sup> have demonstrated strong type 0 resetting with very intense light ( $80,000 \text{ lx}$ , about  $32,000 \mu\text{W cm}^{-2}$ ) and about 12 h duration. The intensity of the light required to elicit a strong phase response curve in *L. maderae* is therefore about two orders of magnitude greater than in *N. cinerea*. Both of these studies, however, show that type 0 response curves can be obtained for 'behavioural rhythms' (presumably using compound eyes as photoreceptors, and having a neural output), provided that the energy of the perturbing signal is sufficiently high.

## Neuronal generation of singing in a cicada

CICADA song may be regarded as a simple rhythmical behaviour because it is highly stereotyped and involves regular spikes in a single pair of motoneurons. It was the subject of an early study of intracellular activity in central neurones<sup>1</sup>. Here I show that the neuronal generator for song of the Australian bladder cicada, *Cystosoma saundersii* (Westw.) is continually active at twice the frequency of motoneurone spikes and, in common with other rhythmical behaviours in arthropods<sup>2–4</sup>, involves non-spiking interneurons.

The song of a cicada is composed of a regular series of sound pulses, each pulse being produced by a snap-like collapse of a stiff ribbed structure, a tymbal<sup>5–8</sup>. There is a tymbal on each side of the anterior of the abdomen. Collapse of a tymbal is caused by a twitch contraction of its tymbal muscle, and the inherent elasticity of the tymbal restores its original shape. Each tymbal muscle is in-

**Fig. 1 a**, Structure of a tymbal motoneurone, viewed dorsally. The abdominal and metathoracic ganglia of *C. saundersii* are fused, and their outline is drawn. The motoneurone was stained by back-filling with dilute (2%)  $\text{CoCl}_2$ . Somata of four interneurons, which were consistently stained by this method—probably trans-synaptically<sup>10</sup>—are also shown. Most of the processes of the motoneurone, as well as its soma, lie near the dorsal surface of the ganglion. **b**, Calling song of *C. saundersii*—sound produced, and simultaneous myogram recorded by a pair of silver electrodes implanted in the left tymbal muscle.

nervated by a single motoneurone, one spike in which is sufficient, in *C. saundersii*, to elicit a twitch contraction of the muscle (*C. saundersii* has neurogenic tymbal muscles; some species have myogenic tymbal muscles<sup>6-8</sup>). Figure 1a shows the geometry of a tymbal motoneurone. The pattern of spikes in tymbal motoneurons during the 'calling' song of *C. saundersii* is shown in Fig. 1b; it is a rather unusual rhythmical activity in that there is a delay of one quarter of a cycle between the spike in one tymbal motoneurone and the spike in its contralateral partner. Either the left or the right tymbal motoneurone may lead and, following short pauses when one or both motoneurons stop spiking, the motoneurons often swap the lead. 'Protest' songs, which a cicada produces when disturbed or when electrical shocks are applied to its brain, are similar although usually of lower spike frequency.

Intracellular recordings from tymbal motoneurons reveal regular, smooth waves in membrane potential (Fig. 2a, b). These waves occur continually, whether or not the cicada is singing. Waves in the left and right motoneurons have the same frequency, which suggests that they originate within a shared oscillator mechanism, but are half a cycle out of phase (Fig. 2a). In recordings from different animals at varying times of day the frequency of the waves ranges from 55 to 80 Hz, although in any particular recording session (up to 2 h) waves have a constant frequency, with only 1 in 200 waves being slightly longer or shorter than usual.

Two sets of observations show that the waves originate in interneurons rather than in the motoneurons them-

**Fig. 2** Intracellular recordings from tymbal motoneurons in a non-singing cicada. Recordings were made with strong glass electrodes filled with 2 M potassium acetate and with resistances 50–80 M $\Omega$ . The electrodes were driven through the intact sheath. In a, recordings are from somata; in other traces they are from unidentified processes. a, Waves recorded simultaneously from left (upper trace) and right (lower trace) tymbal motoneurons. b, Variation in wave amplitude immediately following a period of vigorous singing. c, Effects of passing current into a tymbal motoneurone. Current was passed through the recording electrode by means of a bridge circuit. c, Upper record, depolarising current elicits spikes on top of some waves. The spikes reached the tymbal muscle. Lower record, hyperpolarising current alters the shape but not the frequency of the waves. d, Antidromic spikes which follow, by 9 ms, shocks applied to the tymbal muscle, do not effect the timing or the amplitude of the next wave. Arrow denotes antidromic spike. Calibrations—a, 4 mV, 40 ms; b, 4 mV, 200 ms; c, 40 mV, 40 ms; d, 20 mV, 20 ms.

**Fig. 3** Recordings of phase-locked potentials in tymbal motoneurons and presumed interneurons of non-singing cicadas. a, Intracellular recordings from a tymbal motoneurone (upper trace) and from a non-spiking interneurone (lower trace). b, Intracellular recordings from a tymbal motoneurone (lower) and a non-spiking interneurone (upper). Wave frequency, 65 Hz. c, Hyperpolarising ( $-10$  nA) the interneurone of b alters its waveform and reduces the frequency of waves in it and in the motoneurone to 64.5 Hz. d, An interneurone (upper trace) which spiked once during each wave in a tymbal motoneurone (lower). The neuron is presumed to be an interneurone because no spikes in the motor nerves could be correlated with the frequency of waves in the tymbal motoneurons. e, An interneurone (lower) which spiked twice during each wave in a tymbal motoneurone (upper). Calibrations—a, motoneurone 10 mV, interneurone 1 mV, 40 ms; b, c, interneurone 2 mV, motoneurone 10 mV, 40 ms; d, interneurone 2 mV (a.c., extracellular), motoneurone 20 mV, 20 ms; e, motoneurone 5 mV, interneurone 1 mV, 20 ms.

selves. First, depolarising or hyperpolarising a motoneurone does not alter the frequency of the waves, but can affect their shape (Fig. 2c). Second, an antidromic spike in a tymbal motoneurone does not affect the timing or the amplitude of subsequent waves (Fig. 2d). The motoneurons do not seem to be directly coupled by an electrical or a chemical synapse because an antidromic or orthodromic spike in one tymbal motoneurone produces no recognisable effect on its partner. Each motoneurone receives inputs from different interneurons because there is no significant correlation between the amplitude of a wave in one motoneurone and the amplitude of the next wave in its partner. In the recording from which Fig. 2a is taken, for example, the correlation coefficient for amplitudes of sequential waves in the left and right tymbal motoneurons, calculated by a method of least squares, is 0.275, which is not significant.

Two observations strongly suggest that non-spiking interneurons drive the waves in the motoneurons. First, the waves are very smooth—discrete post-synaptic potentials have never been seen in them. Second, intracellular recordings have been made from a number of non-spiking interneurons with activity phase-locked to the waves in the motoneurons (Fig. 3a, b). The evidence that these neurons were non-spiking interneurons is that neither direct, strong depolarisation nor stimulation of motor axons elicited spikes in them. It is likely that these interneurons are involved in singing because the frequency of the waves in the tymbal motoneurons, which is twice that of spikes during song, is not related to that of any other rhythmical behaviour, such as ventilation, flight or walking. Unfortunately, passing current into an interneurone rarely affected the frequency of the waves, either in the interneurone or in a motoneurone. One exception is shown in Fig. 3b, c, where hyperpolarising the inter-

neurone caused a small but reversible decrease (65–64.5 Hz) in the frequency of waves in both the interneurone and the motoneurone and a change in the waveform in the interneurone. Possibly several interneurons are involved in generating the song rhythm and communicating it to the motoneurons, and passing current into only one interneurone has little effect on the rhythm generator. In addition to the non-spiking interneurons several interneurons which produce spikes phase-locked to the waves in the motoneurons were found (Fig. 3d, e).

When a *C. saundersii* sings each tymbal motoneurone produces a spike on every second wave (Fig. 4a). The frequency of tymbal motoneurone spikes and of sound pulses generated by each tymbal is therefore half that of the waves in the tymbal motoneurons. Because the waves in the left and right motoneurons are exactly out of phase, spikes in them are separated by one quarter of a cycle. Often, in 'protest' songs, spikes occur less regularly than every second potential (Fig. 4b, c)—the rule seems to be that spikes never occur on sequential waves.

The reason for this limit to spike frequency is unclear, but there are three observations which may indicate relevant factors. First, some waves which do not culminate in a spike reach more positive potentials than the take-off potential for spikes (Fig. 4c). Bearing in mind that recordings were probably never made from the spike initiation region of a tymbal motoneurone, the simplest explanation for this is that interneurons other than those

involved in producing the waves in a non-singing cicada are involved in producing spikes. Second, each of the largest waves is often followed by a much smaller one (for example, Fig. 2b). This is not due to direct negative feedback from a motoneurone because an antidromic spike does not affect the amplitude of subsequent waves and there is no correlation between the amplitude of one wave and the amplitude of the wave following it in the same motoneurone (range of serial correlation coefficients for 15 recordings: 0.04 to 0.43). Third, bursts of spikes in a tymbal motoneurone were never seen and even depolarising currents as great as 200 nA injected into a tymbal motoneurone soma produced only single spikes.

It may be a general feature of rhythmical behaviours that their neuronal rhythm generators are continually active. In quiescent locusts the neuronal oscillator for flight produces subthreshold depolarisations at flight frequency in motoneurons<sup>9</sup>. To use a mechanical analogy, nervous systems may well use 'clutches for engaging gear' rather than 'starter motors' in producing rhythmical movements.

**Fig. 4** Intracellular recordings from tymbal motoneurons when a *C. saundersii* is induced to sing by stimulating its brain electrically. *a*, Vigorous singing—spikes alternate with small waves. One large wave, where the spike fails, reaches a more positive potential than the take-off potential for spikes. *b*, Potentials recorded simultaneously from left and right somata. Spikes, identifiable by their sharp rising phase and from the muscle recordings, are rather infrequent, occurring at most on every third wave (left motoneurone). Note that not every large wave gives rise to a spike. *c*, The electrode for this recording had penetrated the ganglion near the origin of the auditory nerve (see Fig. 1). ★, Some waves reach a more positive potential than ●, the take-off potential for spikes. Calibrations—*a*, 40 mV, 40 ms; *b*, *c*, 20 mV, 40 ms.

## Site of *pcd* gene action and Purkinje cell mosaicism in cerebella of chimaeric mice

PURKINJE cell degeneration, *pcd*, is a new autosomal recessive mutation in mice. Affected animals are characterised by a moderate ataxia that results from the postnatal loss of virtually all cerebellar Purkinje cells<sup>1</sup>. We describe here experiments to determine whether the *pcd* gene acts intrinsically within the Purkinje cell or whether the degeneration is secondary to a primary lesion in some other cell type. In this study, experimental chimaeras were made which contained mixtures of mutant (*pcd/pcd*) and genotypically normal (+/+) cells (these chimaeras are denoted *pcd/pcd* ↔ +/+). The results indicate that the *pcd* gene does act within the Purkinje cell. The chimaeras have also been used to examine the surviving population of +/+ Purkinje cells for evidence of clonal development. Surprisingly, these preliminary studies reveal no evidence of clones; the distribution of cells derived from the +/+ component seems random.

The *pcd/pcd* ↔ +/+ chimaeras were produced by Tarkowski<sup>2</sup> and Mintz<sup>3</sup> techniques of aggregation of eight-cell embryos as described previously<sup>4</sup>. Since *pcd/pcd* males are sterile, embryos were obtained from *pcd/pcd* females that were mated to +/*pcd* males so only 50% of the chimaeras were expected to be homozygous for *pcd*. Five chimaeras were produced. One female chimaera was proven to be homozygous for *pcd* by progeny testing. In addition, two male chimaeras were also homozygous for *pcd* as evidenced by their abnormal sperm (a pleiotropic effect of the *pcd* mutation<sup>1</sup>) and loss of cerebellar Purkinje cells. All three *pcd/pcd* ↔ +/+ chimaeras appeared behaviourally normal. They were not, however, subjected to any special behavioural testing.

In all three chimaeras the cerebella were mosaics, for it was obvious in histological sections that many Purkinje cells had degenerated. Although the gene was expressed in the chimaeras,

that is not evidence that it acts within the Purkinje cells. If the *pcd* locus exerts its primary effect within the Purkinje cell and is not cured by the presence of normal cells, then in the chimaera the cells that are *pcd/pcd* will degenerate and the surviving cells will be the  $+/+$  cells. Alternatively, if the degeneration of Purkinje cells is a secondary effect of the *pcd* locus acting in another cell type, then the surviving cells would be a mixture of *pcd/pcd* and  $+/+$  cells. To determine the genotypes of the surviving cells, it is necessary to use an independent cell marker.

One of the *pcd* chimaeras was also chimaeric for the structural gene for  $\beta$ -glucuronidase. This enzyme has been used previously as a cell marker in other tissues<sup>5,6</sup>. In the *pcd* chimaera, the *pcd/pcd* cells were homozygous for *Gus<sup>b</sup>*, the high enzyme activity allele, whereas the  $+/+$  cells were homozygous for *Gus<sup>h</sup>*, the low activity allele. This chimaera is denoted *pcd/pcd Gus<sup>b</sup>/Gus<sup>b</sup> ↔  $+/+$  Gus<sup>h</sup>/Gus<sup>h</sup>*. A new, more sensitive histochemical procedure, developed by Feder<sup>6</sup> was used. This procedure is limited in its use as a central nervous system (CNS) cell marker, but it can be used to determine the genotype of Purkinje cells (R. J. M. and R. L. Sidman, unpublished). In *Gus<sup>b</sup>/Gus<sup>b</sup>* non-chimaeric controls, all of the Purkinje cells show enzyme activity as evidenced by the red reaction product. In *Gus<sup>h</sup>/Gus<sup>h</sup>* non-chimaeric controls, none of the Purkinje cells has sufficient enzyme activity to produce any noticeable staining. In *Gus<sup>b</sup>/Gus<sup>b</sup> ↔ Gus<sup>h</sup>/Gus<sup>h</sup>* chimaeras (both components being  $+/+$  at the *pcd* locus), a mosaic of stained and unstained Purkinje cells is observed (Fig. 1a). Virtually all Purkinje cells can be assigned to one class or the other. When sections from the *pcd/pcd Gus<sup>b</sup>/Gus<sup>b</sup> ↔  $+/+$  Gus<sup>h</sup>/Gus<sup>h</sup>* chimaera were stained by this technique, none of the surviving Purkinje cells showed enzyme activity (Fig. 1b), indicating that they were *Gus<sup>h</sup>/Gus<sup>h</sup>* and therefore  $+/+$  at the *pcd* locus. Thus, in the chimaera, the *pcd/pcd* Purkinje cells have degenerated leaving the genetically normal  $+/+$  cells.

The simplest interpretation of this is that the genic alteration

**Fig. 1** Sagittal sections (7  $\mu$ m) of cerebellar cortex stained histochemically for  $\beta$ -glucuronidase and counterstained with methyl green. The mice were perfused with cold (0–4 °C) 4% formaldehyde in phosphate buffer. The brains were processed and stained as described by Feder<sup>6</sup>. The sections were stained for 3 d at 37 °C with fresh substrate added daily. In these photomicrographs the red precipitate at the sites of glucuronidase activity seems dark gray. *a*, Cerebellar cortex of a *Gus<sup>b</sup>/Gus<sup>b</sup> ↔ Gus<sup>h</sup>/Gus<sup>h</sup>* chimaera. Some of the large Purkinje cells are stained (arrows with dots) indicating they are from the *Gus<sup>b</sup>* component; others are not stained (arrows) and are, therefore, *Gus<sup>h</sup>*. *b*, Cortex of a *pcd/pcd Gus<sup>b</sup>/Gus<sup>b</sup> ↔  $+/+$  Gus<sup>h</sup>/Gus<sup>h</sup>* chimaera. None of the surviving Purkinje cells is stained (arrows) indicating they are from the  $+/+$  *Gus<sup>h</sup>/Gus<sup>h</sup>* component. To the left is a gap left by degenerated Purkinje cells. In both *a* and *b* the other intense staining in the Purkinje cell layer is probably in Golgi epithelial cells (Bergmann glia). Scale bar, 20  $\mu$ m.

**Fig. 2** Distribution of surviving  $+/+$  Purkinje cells in a *pcd/pcd ↔  $+/+$*  chimaera in which 75% of the cells have degenerated. With a drawing tube, the positions of Purkinje cells along the Purkinje cell layer of the lobulus centralis in 20- $\mu$ m sagittal sections were traced on tracing paper. The presence of nuclei and nucleoli were also marked to help eliminate cells present in adjacent sections. After aligning the tracings by superimposition, a map reader was used to measure distances along the Purkinje cell lamina. The positions of the cells were then plotted in straight lines on graph paper. Twenty-five serial sections (500  $\mu$ m) were recorded. The size of the dots is scaled to the average Purkinje cell diameter. Thus, the figure represents the location of cells as they would appear if the folium was flattened out and viewed from above. A two-dimensional reconstruction such as this might change the shape of a patch or clone of cells, but it would not disrupt it. Throughout the rest of the cerebellum of this chimaera, the proportion of cells that survived was relatively constant; there were no regions where the density of Purkinje cells was normal and no regions where they had all degenerated. Thus, the portion reconstructed is not at an interface between large patches of mutant and normal cells. Scale bar, 100  $\mu$ m.

at the *pcd* locus is affecting the Purkinje cell directly. This conclusion is supported by an ultrastructural study of *pcd/pcd* Purkinje cells in which a unique series of abnormalities in Purkinje cells was observed. Nothing was observed in this earlier study that would suggest the gene was acting anywhere else in the cerebellum other than the Purkinje cell<sup>7</sup>. One alternative is that the *pcd* locus is acting in some other cell, also of the *pcd/pcd* genotype, with which the Purkinje cell must interact. This seems highly unlikely, for at least some *pcd/pcd* Purkinje cells should have been close enough to  $+/+$  cells of this 'other' cell type during development to be saved, but none was.

Since the surviving Purkinje cells in the chimaera are all of the same genotype, they had, at some time in development, common ancestors. Their distribution can be studied for evidence of clones that might be of developmental, anatomical and/or functional significance. In single sections the mosaicism is apparently extremely fine with some 'patches' being a single cell. This, however, must be cautiously interpreted, as what seems to be a single, isolated cell could be on the edge of a much larger patch or there could be narrow clones running perpendicular to the plane of section. The Purkinje cell layer is relatively well-suited for serial reconstruction for it is a single cell-thick lamina so the positions of cells can be plotted in two dimensions. A serial reconstruction showing the distribution of surviving Purkinje cells in a portion of the central lobule (lobulus centralis<sup>8</sup>) of one of the *pcd* chimaeras is shown in Fig. 2. There does not seem to be any pattern or evidence of clones; the distribution seems to be random.

Although it might seem unlikely, the random distribution could be the result of rearrangement of the  $+/+$  cells after the *pcd/pcd* cells degenerate. This possibility was investigated by examining chimaeras in which there was no cell loss but in which the genotype of Purkinje cells was determined with the  $\beta$ -glucuronidase cell marking technique. Sections from a *Gus<sup>b</sup>/Gus<sup>b</sup> ↔ Gus<sup>h</sup>/Gus<sup>h</sup>* chimaera were analysed to estimate the number of cells in a clone of Purkinje cells. The estimate is based on a comparison of the mean patch size (contiguous

**Table 1** Mean patch size and estimate of clone size for *Gus<sup>b</sup>/Gus<sup>b</sup>* Purkinje cells in a *Gus<sup>b</sup>/Gus<sup>b</sup> ↔ Gus<sup>b</sup>/Gus<sup>h</sup>* chimera.

Mean no. of <i>Gus<sup>b</sup>/Gus<sup>b</sup></i> cells per patch				
1.245 ± 0.071	1.367 ± 0.100	1.196 ± 0.051	1.298 ± 0.091	1.217 ± 0.063
Cells				
Observed mean patch size (total)	1.259 ± 0.033			
Expected in random linear array	1.212			
Clone (observed/expected)	1.030 ± 0.021			

Each of the five means is based on a complete sagittal section through the vermis of a chimera in which 17.5% of the cells were *Gus<sup>b</sup>/Gus<sup>b</sup>* (that is, stained). A total of 1,947 cells were scored. There were 270 patches (that is, groups of contiguous cells of like genotype). The mean patch size expected in a random linear array is estimated by  $1/(1-p)$  where  $p$  is the proportion of cells of that genotype in the population ( $p_{Gus^b} = 0.175$ ). For an approximation of the number of cells per patch in a two-dimensional array, the numbers could be squared. That would not, however, alter the conclusion that the distribution is near random.

cells of like genotype) with the mean expected in a random array<sup>9</sup>. In a purely random array, there would be one cell per clone. The data, shown in Table 1, yield an estimate of 1.03 Purkinje cells per clone. Thus, even in chimaeras in which there is no cell loss, the Purkinje cells seem to be almost randomly distributed. A fine-grained mosaicism has also been observed by Dewey *et al.*<sup>10</sup> using other cell marking techniques.

These studies indicate that in the cerebellum the *pcd* locus exerts its primary effect within the Purkinje cell. The *pcd* locus is pleiotropic; its other effects include loss of retinal photoreceptor cells<sup>11</sup>, mitral cells in the olfactory bulbs<sup>1</sup> and males have abnormal (or degenerating) sperm<sup>1</sup>. These other effects were expressed in the chimaeras, but it could not be determined whether the *pcd* locus was also acting directly within those cell types.

It is well established that most cortical neurones, including Purkinje cells, are born in germinal centres such as the embryonic ventricular zone and then migrate to the position they will occupy in the adult cortex<sup>12</sup>. Although they do migrate, the migration seems to be radial and one might expect that daughter cells would remain in proximity to one another which would give rise to clones of cells of the same genotype in adults. In this study, and in others<sup>10,13</sup>, however, there is little evidence of clones which suggests that at some time in development there must be a considerable amount of cell mixing. Additional studies are obviously needed to confirm this finding and to determine when the mixing occurs. It will also be of interest to examine other cell types for Purkinje cells are unusual in that they are spread out into a single cell lamina during the massive growth and foliation of the cerebellum.

## Selective expression of xenotropic virus in congenic HRS/J (hairless) mice

GENETIC factors strongly influence susceptibility to leukaemia in mice. In some instances leukaemogenesis hinges on only a few genes, or even a single gene<sup>1</sup>. The hairless mutation is an example of this. Homozygotes for this autosomal recessive gene (*hr/hr*) have a high incidence of thymic leukaemia (45% at 8–10 months), whereas the incidence in heterozygotes (*hr/+*) is low (1% at 8–10 months)<sup>2</sup>. The leukaemogenic effect produced by homozygosity for *hr* is unknown. Here we report that thymuses of *hr/hr* mice produce high titres of xenotropic viruses, whereas thymuses of *hr/+* mice do not. Furthermore, viruses with a broadened host range were isolated from thymuses of preleukaemic *hr/hr* mice, but not from any tissue of *hr/+* mice. We propose that the mutant gene *hr* specifies circumstances that augment production of xenotropic virus by the thymus. This phenomenon may be an important step in the development of thymic leukaemia.

The virology of *hr/hr* and *hr/+* mice has not been extensively studied. Using a complement fixation test, Meier's group found that adult and embryo tissues of both homozygotes and heterozygotes contained similar amounts of murine leukaemia virus antigen<sup>3</sup>. But, using an XC plaque assay to test tail extracts the same authors later reported that the *hr/hr* mouse expressed several times higher amounts of ecotropic Type C virus than the *hr/+* animal<sup>3</sup>.

In a preliminary experiment we found that the ecotropic virus in HRS/J mice, the strain that carries the *hr* gene, was N-tropic. Therefore, we measured ecotropic virus in a modified XC plaque assay using NIH-3T3 cells<sup>4</sup>. As shown in Fig. 1a, N-tropic virus was readily detected in spleen, thymus, and bone marrow of both *hr/hr* and *hr/+* mice. Titres of virus increased with age, most notably in the thymus. But, at no time was there a difference in titre of infectious ecotropic virus between the two types of mice. It is therefore unlikely that the difference in the incidence of leukaemia can be explained by a difference in the expression of ecotropic virus.

Xenotropic virus was assayed by a focus-induction assay in Moloney sarcoma virus-transformed, non-producer cat cells<sup>5</sup> and a fluorescent antibody focus method involving mink lung cells<sup>6</sup>. With the cat cell assay, we detected small amounts of xenotropic virus in thymuses of 2-month-old mice, but there was no difference between *hr/hr* and *hr/+* mice at this age (Fig. 1b). The titre of xenotropic virus in thymuses of 8-month-old *hr/hr* mice increased remarkably, however, whereas virtually no increase was found in *hr/+* mice. Low titres of xenotropic virus were also found in spleen and bone marrow of some *hr/hr* and *hr/+* mice. Therefore, increased expression of xenotropic virus was specifically related to the age, tissue and genotype of the mouse.

We confirmed this observation with the mink cell assay (Fig. 1c): at 8 months of age the expression of xenotropic virus in thymuses of *hr/hr* mice was, on the average, 100 times more than that in thymuses of *hr/+* mice. In other tissue, low titres of xenotropic virus were occasionally detected. We failed to find any clear-cut morphological changes in the infected mink cells.

We next characterised further the xenotropic virus that infected the mink cells. After several *in vitro* passages of the infected mink cells, the supernatant was filtered (Millipore, 45 µm) and used to infect fresh mink cells. After three or four more passages the culture supernatant was filtered and tested for infectivity on both mink and NIH-3T3 cells by means of the XC-plaque assay and the fluorescent antibody focus method. None of 48 isolates produced XC plaques on either NIH-3T3 or mink cells; 46/48 isolates

were pure xenotropic virus in that they failed to infect mouse cells, but readily infected mink cells (Table 1). But, 2/7 isolates from thymuses of 8-month-old *hr/hr* mice infected both mouse and mink cells. Although we have not yet cloned the latter isolates, it is unlikely that they are

simple mixtures of ecotropic and xenotropic viruses because: (1) they were infectious in mouse cells after having been passed more than 10 times in mink cells, and (2) they were totally negative in the XC test. We refer to these viruses as polytropic because of their broad host range and to

**Fig. 1** Expression of endogenous viruses in HRS/J mice. Ecotropic and xenotropic viruses were quantitated by infectious centre assays; titres were expressed as  $\log_{10}$  of the number of plaques or foci per  $10^7$  cells used in the assay. Black columns represent the virus titres of *hr/hr* mice and open columns those of *hr/+* mice. *a*, Ecotropic virus. In this assay<sup>4</sup>,  $2 \times 10^5$  NIH-3T3 cells were plated in a 60-mm plastic Petri dish; 24 h later, the monolayer was treated with 2 ml of  $25 \mu\text{g ml}^{-1}$  DEAE-dextran for 60 min at  $37^\circ\text{C}$ , rinsed, and infected with serial dilutions of washed lymphoid cells. After 5 d the infected indicator cells were exposed to ultraviolet light and overlaid with  $1 \times 10^6$  XC cells. Two days later, the culture was methanol-fixed and Giemsa-stained and the number of plaques was counted. The medium was  $4 \times$  Eagle's minimum essential medium with 10% unheated foetal calf serum. *b*, Xenotropic virus detected by the cat cell assay<sup>6</sup>. The indicator cat cell (8C) monolayer was prepared as above, treated with DEAE-dextran for 30 min, rinsed and infected. Transformed cell foci produced by rescued MSV pseudotypes were counted 12 days after infection. The medium was McCoy's 5A medium with 15% heat-inactivated foetal calf serum. *c*, Xenotropic virus by the mink cell assay<sup>6</sup>. Preparation of the indicator cell monolayer and method of infection was the same as in *b*. Cultures were made in duplicate; one with  $20 \times 20$  mm coverslip and another without. On the fifth day, cells on the coverslip were acetone-fixed and stained with fluorescein isothiocyanate conjugated goat antiserum against Moloney virus (lot 5010101, NCI). Cultures without coverslips were maintained for 7–10 d to study possible morphological changes in infected mink cells and for subsequent isolation of the virus. The medium was McCoy's 5A medium with 10% unheated foetal calf serum. In all the infectious centre assays *in vitro*, medium was changed at 2–4 d intervals.

Table 1 Isolation of polytropic virus

Genotype	Age (months)	Polytropic/xenotropic		
		Thymus	Spleen	Bone marrow
<i>hr/hr</i>	2	0/2	0/3	0/3
	8	2/7	0/4	0/1
	Leukaemic	0/5	0/2	
<i>hr/+</i>	2	0/2	0/3	0/4
	8	0/3	0/1	0/3
	Leukaemic	0/2	0/3	

distinguish them from the amphotropic viruses of wild mice<sup>7</sup>. In a preliminary experiment, both an ecotropic and a xenotropic virus interfered with the infectivity of the polytropic virus for mouse and mink cells, respectively (data not shown). The polytropic isolates produced subtle morphological changes in infected mink cells, such as piling-up of cells or tiny cytoplasmic vacuolations, but these changes were not as clear as those reported by Hartley *et al.*<sup>8</sup> with the analogous AKR virus. Results of further characterisation of the polytropic isolates will be reported elsewhere. Several xenotropic isolates obtained from leukaemic tissue were also studied; none of the 12 samples was polytropic.

Titres of ecotropic and xenotropic viruses in leukaemic tissues of *hr/hr* and *hr/+* mice are shown in Fig. 2. There were no significant differences in titres of ecotropic virus between preleukaemic and leukaemic thymic tissues. By contrast, leukaemic thymic tissue had much lower titres of xenotropic virus than preleukaemic thymus tissue. These findings may be explained either by regulation of expression of the virus at different stages of leukaemogenesis or by a shift in cell types in the thymus.

Our results are comparable to those of Hartley *et al.*<sup>8</sup> in the AKR mouse. These workers demonstrated an increased

expression of xenotropic virus in thymuses of preleukaemic AKR mice<sup>8</sup>. Some isolates of this virus were polytropic and probably represent recombinant viruses<sup>8</sup>. The polytropic virus obtained from AKR mice produced no plaques in the XC test but productively infected mouse cells, as determined by an immunofluorescent method. The virus we obtained from hairless mice had similar properties. There are other similarities between the AKR and hairless systems: titres of ecotropic virus are high in all three types of mice; in contrast, expression of xenotropic and polytropic viruses is observed specifically in thymuses of AKR and *hr/hr* mice, but not in the *hr/+* mouse.

We stress here the outstanding advantage of the hairless mouse system: it is congenic, thus providing internal controls for analyses of the effects of one or at most very few genes in viral leukaemogenesis. Our results suggest that one effect of the mutant gene is to augment the production of xenotropic virus by the thymus. Genetic recombination between this agent and an ecotropic virus may give rise to the polytropic virus we detected. Experiments to test the oncogenicity of the latter agent are in progress.

## A feline leukaemia virus- and sarcoma virus-induced tumour-specific antigen

BIOCHEMICAL and immunological methods of distinguishing between normal and malignant cells have had limited success. When studying cellular transformation, it is advantageous to study tumour viruses since they contain a definable quantity of genetic information for viral replication and for cell transformation. Viral gene products, such as viral structural antigens, can be studied in both normal infected and virus-transformed cells. Oncornavirus antigens are found in the cytoplasm and cell membrane of both normal and transformed infected cells<sup>1,2</sup>. These antigens are glycoproteins of the viral envelope or are internal viral proteins<sup>3-5</sup>. Non-viral tumour-specific antigens resulting from transformation of the host cell by the causative virus, are found in the tumour cell membrane of some tumours induced experimentally by polyoma<sup>6</sup> and SV40<sup>7</sup> DNA viruses; and in cells transformed by an oncornavirus, the Rous sarcoma virus<sup>8,9</sup>, but have not yet been found in any oncornavirus-induced leukaemic cell. Lymphosarcoma (LSA) or leukaemia of pet cats is caused by a contagiously spread oncornavirus, the feline leukaemia virus (FeLV)<sup>10</sup>. Antibody to the feline oncornavirus-associated cell membrane antigen (FOCMA)<sup>11,12</sup> is associated with resistance to LSA development in FeLV-infected pet cats<sup>13,14</sup> and with regression of feline sarcoma virus (FeSV) experimentally-induced fibrosarcomas<sup>15</sup>. To

**Fig. 1** Viable cell IFA tests for FOCMA and fixed cell IFA tests for intracytoplasmic FeLV antigens of cat cells. Normal feline leukocytes: *a*, FeLV antigen negative; *b*, FOCMA negative. Normal feline leukocytes: *c*, FeLV antigen positive; *d*, FOCMA negative. Lymphosarcoma cells: *e*, FeLV antigen positive; *f*, FOCMA positive. Lymphosarcoma cells: *g*, FeLV antigen negative; *h*, FOCMA positive. In the direct FOCMA test a 0.05ml aliquot of a  $15 \times 10^6$  ml<sup>-1</sup> washed cell suspension was incubated at 4 °C for 30 min with 0.05 ml 1:4 dilution of FeLV-infected cat serum which had a high titre (1:32) of antibody to FOCMA, but which had no FeLV-neutralising antibody. As a control, another 0.05ml aliquot of a washed cell suspension was incubated, in the same conditions, with 0.05 ml cat serum containing no FOCMA antibodies. After incubation, the cells were washed twice, mixed with the fluorescein isothiocyanate-conjugated rabbit anti-cat serum globulin (Sylvania, Millburn, New Jersey), diluted 1:10, and allowed to react on ice for 30 min. Cells were then washed twice and resuspended in 0.05 ml 50% glycerol in PBS. A minimum of 100 cells were counted from each cell preparation. When 50% of the cells had punctate membrane fluorescence, and when the number of cells fluorescing in the FOCMA test was at least 25% greater than the number of fluorescing B cells from the same preparation, the cat was considered to have FOCMA-positive lymphoid cells (that is, the cells were lymphoid tumour cells). In the FOCMA absorption test, an aliquot of the cat anti-FOCMA serum was used at two double dilutions below the 50% fluorescent endpoint. The diluted serum was then absorbed twice for 30 min each at 4 and 37 °C with an equal volume (a minimum of 0.2 ml) of washed packed test cells. The residual FOCMA antibody titre of the absorbed cat anti-FOCMA serum was then determined in a direct FOCMA test as described previously, and compared with that of unabsorbed (control) serum from the same aliquot. A 25% or greater reduction in the FOCMA antibody titre of the absorbed serum was considered a positive absorption, indicating that FOCMA was present on the B lymphoid cells and that these cells were tumour cells.

determine whether FOCMA is a tumour-specific antigen, we tested normal, LSA and fibrosarcoma cat cells for both FeLV antigens and FOCMA. We report here that FOCMA is a tumour-specific antigen induced by naturally occurring feline leukaemia and sarcoma viruses. Our observation, which was made in a random bred species, the pet cat, may have particular relevance for the diagnosis and therapy of naturally occurring lymphoid tumours of other animals, including man.

Cells from both FeLV-infected and uninfected healthy pet cats, and FeLV-infected and uninfected cats with naturally occurring LSA, were studied. All cells were tested for cytoplasmic FeLV structural antigens by the fixed cell immunofluorescent antibody (IFA) test<sup>16</sup>. Detection of FeLV antigens in the cytoplasm indicates that FeLV is replicating in these cells and that FeLV gp70 and p30 are present in their cell membranes<sup>4,5,16</sup>.

To determine whether FOCMA is expressed on lymphoid cells regardless of their cellular origin, tests to determine whether the cells were of T or B cell origin were also carried out. Lymphocytes were tested for their ability to form rosettes with guinea pig erythrocytes to determine whether they were of T cell origin, and for the presence of cell surface immunoglobulins (Ig) to determine whether they were of B cell origin<sup>17</sup>.

Two tests for FOCMA were carried out, the direct test and the absorption test using a standard reference serum (see Fig. 1)<sup>11,12</sup>. This reference serum was obtained from an FeLV-infected cat and contained FOCMA antibody at a titre of 1:32 but did not contain FeLV-neutralising antibody. The FOCMA reactivity of the serum could not be absorbed out with intact or disrupted FeLV, with purified FeLV gp70 or p30<sup>18,19</sup>, with foetal cat cells, or with normal cat lymphoid cells. FOCMA antibody was absorbed only by FeLV-producing or non-producing feline LSA cells. If the lymphoid cells were found to be of B cell origin they were tested for FOCMA by the absorption test. This was necessary since the fluorescein-conjugated rabbit anti-cat serum globulin used in the direct FOCMA test reacts with Ig-producing B cells and thus makes interpretation of the direct test impossible.

A total of 36 cats with histological diagnoses of LSA were studied. Twenty-seven of the cats had FeLV-producing LSA cells, whereas the LSA cells of the other nine cats were not replicating FeLV. Twenty-three out of the 36 LSAs (64%) were of T cell origin (Table 1). All 12 thymic LSAs and 10 of the 18 multicentric LSAs were T cell tumours. Both T and B cell markers were present in seven of the LSAs and were classified as mixed cell tumours. Only four LSAs were of B cell origin and three of these were LSAs of the gastrointestinal tract. No lymphocyte cell surface markers could be detected in two LSAs and these were classified as null cell tumours.

All 33 FeLV-producing LSA cell preparations obtained from 27 FeLV-infected LSA cats were positive for FOCMA (Table 2). Similarly, all 13 LSA cell preparations, which were not replicating FeLV, obtained from nine FeLV IFA test-negative LSA cats were also FOCMA positive. FOCMA was expressed on lymphoid tumour cells (Fig. 1) regardless

of their FeLV status and T, B, mixed or null cell origin. By contrast, four out of four FeLV-infected and four out of four FeLV-negative morphologically normal lymphocyte preparations, which were obtained from the peripheral blood of cats with LSA who had no evidence of circulating leukaemic cells, were negative for FOCMA. A total of 63 normal cell preparations, 20 FeLV-infected and 43 FeLV uninfected, obtained from healthy cats were negative for FOCMA. Normal lymphocytes from 11 FeLV-infected and 22 uninfected cats were FOCMA negative. Infected neutrophils from six healthy cats and infected thymocytes from three foetuses were FOCMA negative. Uninfected neutrophils (eight cats), thymocytes (five cats), splenocytes (five cats) and myelocytes (three cats) were also negative for FOCMA.

Normal FeLV-infected and uninfected feline embryo lung fibroblast cell cultures were negative for FOCMA. Similarly, three non-lymphoid feline tumour cell cultures (one mammary adenocarcinoma, one osteosarcoma, and one anaplastic sarcoma) were also negative for FOCMA. Two fibrosarcoma cultures obtained from young cats with naturally occurring multicentric FeSV fibrosarcomas and granulocytic tumour cells from a cat with myelogenous leukaemia were, however, FOCMA positive, as was a dog fibrosarcoma culture from an FeSV-induced fibrosarcoma in a beagle puppy.

Our findings indicate that FOCMA is an FeLV- or FeSV-induced tumour-specific antigen expressed on the membranes of naturally occurring feline LSA, myelogenous leukaemia and multicentric fibrosarcoma cells. The finding that myelogenous leukaemia cells are FOCMA positive is important, since it indicates that FeLV can transform granulocytes in addition to lymphocytes. Since FOCMA has been induced by FeSV in cells of other species<sup>20</sup>, it is unlikely that FOCMA is an expression of an activated feline cellular gene. The expression of FOCMA on the membranes of FeLV non-producer feline LSA cells enables these cells to be used to study a defective leukaemia virus of a naturally occurring LSA. Such cells will be valuable

for comparative studies of lymphoid tumours of all animals, including man.

## Role of sendai virus fusion-glycoprotein in target cell susceptibility to cytotoxic T cells

In mice, cytotoxic T lymphocytes (CTLs) are generated *in vivo* or *in vitro* against virally-infected syngeneic cells<sup>1–4</sup>. The specificity of killing requires that the target cells possess both viral gene product(s) and H-2K and/or D gene products which are identical to those on the effector cells<sup>5</sup>. Target cells coated with non-infectious (ultraviolet-inactivated) Sendai virus are also specifically lysed by syngeneic virus-specific CTLs<sup>6</sup>. We show here that it is primarily the fusion glycoprotein of the Sendai virus envelope which is essential for the formation of the target antigen on cells coated with ultraviolet-inactivated Sendai virus.

The Nagoya strain of Sendai virus (from Dr H. Tozawa, Kitasato University, Japan), grown in 10-d-old embryonated chicken eggs, was purified and inactivated by exposure to ultra-

violet light. Ultraviolet-treated Sendai virus (SVuv) shows no infectivity ( $<5$  PFU per ml, no plaques for a 0.2 ml undiluted sample) in primary rhesus monkey kidney cells and also no detectable synthesis of viral proteins in coated P815 (H-2<sup>d</sup>) mouse mastocytoma cells (from Dr B. Smith, Institute for Cancer Research, Philadelphia) at 24 h after coating with virus as measured by direct FITC-antibody (Microbiological Associates), staining (data not shown). For the selective digestion of the fusion glycoprotein of the Sendai viral envelope, SVuv was treated with trypsin  $20 \mu\text{g ml}^{-1}$  according to the method of Shimizu *et al.*<sup>7</sup>.

Table 1 shows that trypsin treatment of SVuv resulted in an 88% decrease in cell-fusion activity and an approximately 95% decrease in haemolytic activity. Thus, trypsin inactivates the Sendai virus fusion and haemolytic activities, both of which reside on the viral fusion glycoprotein (referred to as the F glycoprotein)<sup>8</sup>. On the other hand, trypsin did not affect the viral haemagglutinin (HA) and neuraminidase (NA) activities which are both known to reside on the only other viral glycoprotein (referred to as the HANA glycoprotein)<sup>8</sup> (Table 1). Results similar to these have also been observed by Shimizu *et al.*<sup>9</sup>. Thus, the two ultraviolet-treated Sendai virus preparations used for coating target cells differed in that one possessed the functional activities of the F glycoprotein (referred to as SVf<sup>+</sup>) and the other lacked the functional activities of the F glycoprotein following trypsin digestion (referred to as SVf<sup>-</sup>).

Sendai virus-specific cytotoxic effector cells were prepared using a modification of the method of Schrader *et al.*<sup>6</sup>. DBA/2J (H-2<sup>d</sup>) mouse spleen cells, which had been primed *in vivo* with SVuv, were re-stimulated *in vitro* with  $\gamma$ -irradiated syngeneic spleen cells coated with SVuv. As a control, normal (unprimed) DBA/2J spleen cells were co-cultured with  $\gamma$ -irradiated normal C3H/HeJ (H-2<sup>k</sup>) mouse spleen cells. Only SVf<sup>+</sup> coated syngeneic P815 (H-2<sup>d</sup>) cells were killed significantly by Sendai virus-specific sensitised DBA spleen cells. SVf<sup>-</sup>-coated and mock-infected P815 targets were not killed significantly by the effector cells (Fig. 1). Effector cells stimulated *in vitro* with normal allogeneic (C3H/HeJ) spleen cells did not significantly lyse the P815 target cells (Fig. 1). Therefore, the virus-specific lympholysis was not due to nonspecific killing caused by effector cells binding to target cells by Sendai virus bridges. After the *in vitro* generation, treatment of effector cells with anti-Thy-1.2 and complement showed that SVuv-specific killing was due to T cells (data not shown). These experiments were

**Fig. 1** Susceptibilities of P815 target cells coated with SVf<sup>+</sup> or SVf<sup>-</sup> to Sendai virus-specific CTLs. DBA/2J mice were primed *in vivo* with a single injection of 100–200 haemagglutinating units (HAU) of SVuv per mouse 3 weeks before collection of spleen cells.  $5 \times 10^7$  spleen cells were cultured with  $3 \times 10^7$  unprimed DBA/2J spleen cells pretreated with  $\text{NH}_4\text{Cl}$  to remove red blood cells, coated with SVuv at a concentration of 100–200 HAU per  $1 \times 10^7$  cells (as described below), and  $\gamma$ -irradiated at 2,000 R. Using the procedure described above, unprimed DBA spleen cells were cultured with  $5 \times 10^7$  normal C3H/HeJ spleen cells. The culture medium consisted of EHAA<sup>11</sup> supplemented with  $5 \times 10^{-5}$  M 2-mercaptoethanol and 5% heat-inactivated foetal calf serum. Effector cells were collected 6 d later from cultures containing the virus-coated syngeneic stimulating cells (—) and the allogeneic stimulating cells (---) by using Ficoll-Isopaque fractionation to remove red cells and dead cells<sup>12</sup>. Target cells were prepared as follows: <sup>51</sup>Cr-labelled P815 cells were treated at 4 °C for 1 h with SVf<sup>+</sup> in PBS (○), SVf<sup>-</sup> in PBS (△), or PBS (□) at 200 HAU per  $1 \times 10^7$  cells. The cells were then washed twice with PBS. Cytotoxicity assays were performed in round bottom-wells of a microplate (Linbro) with  $1 \times 10^4$  target cells and a given number of effector cells per well and were allowed to react for 6 h. The data are plotted as % <sup>51</sup>Cr-release for triplicate wells. The indicated s.d. was always less than 5%. The spontaneous release of all targets was 23–26%. Percentage cytotoxicity was calculated as follows:  

$$\frac{\text{c.p.m. experimental release} - \text{c.p.m. spontaneous release} \times 100}{\text{c.p.m. maximum release} - \text{c.p.m. spontaneous release}}$$

**Table 1** Effects of trypsin treatment on Sendai virus envelope activities

Sendai virus	HAU per ml	NAU per ml	% Cell fusion	% Haemolysis
Trypsin treated	1,900	58	12	4.8
Untreated	1,900	56	100	100

Sendai virus grown in embryonated chicken eggs was purified by discontinuous sucrose gradient (20% and 50% (w/w)) centrifugation and resuspended in phosphate-buffered saline (PBS) (pH 7.2). Aliquots of 2 ml of purified virus were irradiated in the ultraviolet at  $800 \mu\text{W cm}^{-2}$  for 30 min with continuous rocking in a plastic dish (Falcon 3002). The ultraviolet-inactivated virus was treated with trypsin (DCC treated bovine pancreatic trypsin, Sigma) at a final concentration of  $20 \mu\text{g ml}^{-1}$  at 36 °C for 30 min. Trypsin was removed by centrifugation at  $55,000g$  for 30 min at 4 °C and the trypsin-treated (SVf<sup>-</sup>) and untreated virus (SVf<sup>+</sup>) were each resuspended in PBS. Haemagglutination (HA), neuraminidase (NA) and haemolytic assays were carried out as described previously<sup>10</sup>. The cell fusion activities of the virus preparations were expressed as the percentage decrease in the total number of cells in the virus-infected cultures (compared to mock-infected control cultures) due to the cell-to-cell fusions. For cell fusion measurements, replicate cultures of HeLa cells (seeded 1 day previously at  $2 \times 10^6$  cells per 60 mm plastic Petri dish) were inoculated with 0.5 ml of SVf<sup>+</sup>, SVf<sup>-</sup>, or mock-infected. Following a 1 h virus adsorption, the cultures were overlaid with 5.0 ml of media containing 10% foetal calf serum. Total cell numbers were measured 2 h later.

repeated three times with identical results to those shown in Fig. 1. Thus, the Sendai virus F glycoprotein is the primary virus component necessary for the lysis of ultraviolet-inactivated virus-coated target cells by syngeneic CTLs.

Treatment of the Sendai virion with trypsin causes selective proteolytic cleavage(s) of the F glycoprotein<sup>7</sup> and inactivates its biological activities of fusion and haemolysis (Table 1 and ref. 9) with no detectable effect on the amount of viral HANA glycoprotein on the virus-coated cells. Table 2 shows that there is no significant difference in the cell-associated NA activities between SVf<sup>+</sup>- and SVf<sup>-</sup>-coated cells for at least 6 h after virus coating, which corresponds exactly to the cytotoxicity reaction time (Fig. 1). Similar results to those in Table 2 were obtained in a repeat experiment. These experiments rule out the possi-

**Table 2** Neuraminidase activities of Sendai virus-coated P815 target cells

Time after coating cells (h)	Neuraminidase activity ( $A_{540}$ ) from cells coated with		
	SVf <sup>+</sup>	SVf <sup>-</sup>	No virus
0	0.462	0.491	0.112
3	0.229	0.326	0.112
6	0.223	0.275	0.111

P815 cells were treated with SVf<sup>+</sup> in PBS, SVf<sup>-</sup> in PBS, or PBS in the conditions described for the labelled target cell preparations (see Fig. 1 legend). After washing, the cells were incubated at 37 °C in the culture medium for the indicated times. Following incubation,  $2.4 \times 10^6$  cells were pelleted and assayed for cell-associated viral neuraminidase activity using the assay method used for Sendai virions<sup>10</sup>.

bility that there is a difference in the amount of adsorbed viral HANA glycoprotein on the target cells coated with either SVf<sup>+</sup> or SVf<sup>-</sup>, that is, that fusion activity determines the amount of virus adsorbed to the cell surface in these conditions.

During the course of these studies, Koszinowski *et al.*<sup>13</sup> reported that target cells coated with a partially purified envelope fraction (containing both HANA and F glycoproteins from disrupted Sendai virions) were susceptible to syngeneic virus-specific CTLs. Thus, our studies confirm and extend these results by showing that it is the F glycoprotein of the Sendai virus envelope that has an essential role in the formation of the target antigen on the inactivated virus-coated target cells recognised by the syngeneic (ultraviolet-inactivated Sendai virus-specific) CTLs.

Two general hypotheses have been proposed to explain H-2 restriction in virus-specific lymphocyte cytotoxicity<sup>14</sup>. The CTLs could recognise the H-2K and/or D gene products which are modified by the virus (altered-self hypothesis) or the CTLs could recognise both H-2 and viral gene products (dual recognition hypothesis). Recently, Ennis *et al.*<sup>15</sup> reported experiments which support the dual recognition of both H-2 and viral haemagglutinin antigens for influenza virus-specific CTLs. It is not known whether the H-2 and viral antigens were recognised by two separate receptors, one for the H-2 antigen and the other for the influenza virus haemagglutinin antigen, or whether there could be one receptor specific for some structural association between these two antigens<sup>14</sup>. A possible structural association of H-2 and murine leukaemia virus envelope glycoprotein on the surface of mouse tumour cells producing murine leukaemia virus has been suggested from co-capping and co-patching studies<sup>16</sup>.

There are several possible ways of explaining the role of the F glycoprotein in the Sendai virus-specific cytotoxic reaction. The fusion activity of the ultraviolet-inactivated Sendai virus may be required for an association of H-2 gene products and virion component(s). It is believed that Sendai virion components can disperse quickly throughout the cell membrane after fusion of the viral envelopes<sup>17</sup>. Following the dispersion of Sendai virion components, the F glycoprotein itself and/or other viral gene products could interact with H-2 gene products in the cell membrane. Alternatively, the fusion glycoprotein itself could directly become a part of the target antigen without the expression of its fusion activity.

Experiments are in progress to discriminate between these various possibilities by using purified subcomponents isolated from Sendai virions. We are also investigating the possibility that in conditions where cells are infected with live (not ultraviolet-inactivated) viruses other virion or viral-induced component(s) could also contribute to the formation of the target antigens recognised by syngeneic virus-immune CTLs.

## Isolation of separate Fc receptors for IgG complexed to antigen and native IgG from a murine leukaemia

RECENT studies have suggested that membrane receptors for the Fc region of IgG (Fc receptors) may be heterogeneous structures with distinctive binding properties<sup>1-5</sup>. Walker has reported that a single cell line may possess separate Fc receptors for IgG molecules of different subclass<sup>1</sup>, and Heusser *et al.* have demonstrated that macrophage-like cell lines may possess two distinct receptors: one which binds monomeric IgG2a, and another which binds to aggregates of all subclasses<sup>2</sup>. Unkeless recently reported that a variant clone of the P388D1 mouse macrophage line had the same number of binding sites for IgG2a as the parent line, but only 10% of the binding sites for rabbit IgG in the form of soluble antigen-antibody complexes, suggesting the presence of two distinct Fc receptors<sup>3</sup>. The molecular identity of Fc receptors remains uncertain since few structural studies defining these membrane components are currently available<sup>6-8</sup>. In this study we demonstrate that several glycoproteins with Fc binding activity can be isolated from the plasma membranes of L1210 cells, and provide structural evidence that separate receptors may be responsible for binding IgG which has been complexed with antigen, and monomeric or aggregated IgG.

The murine leukaemia L1210 was grown in stationary culture in RPMI 1640 supplemented with 10% foetal calf serum (Flow Laboratories, Rockville, Maryland). Cells ( $2 \times 10^{10}$ ) were swelled in hypotonic buffer and ruptured in a Ten Broeck homogeniser. The plasma membranes were prepared by a partition of the cell lysates in a two-phase system of polyethylene glycol and dextran<sup>9</sup>. The glycoproteins were extracted from the plasma membranes using 0.3 M lithium diiodosalicylate as described by Marchesi and Andrews<sup>10</sup>. In some experiments, the cells were labelled with <sup>125</sup>I using lactoperoxidase-catalysed iodination before lysing, and in other experiments the glycoproteins were labelled with <sup>125</sup>I by the chloramine-T method<sup>11</sup> after the extraction. In the two experiments in which lactoperoxidase-catalysed iodination was used, 39% and 46% of the cell-associated counts were recovered in the plasma membrane interphase, and 43% of the plasma membrane-

associated counts were recovered in the glycoprotein extract. The results obtained using the two labelling techniques were identical.

The glycoprotein extract obtained from  $2 \times 10^{10}$  cells contained approximately 2 mg protein and seemed to have Fc receptor activity since it was bound by erythrocytes coated with IgG antibody, but not by erythrocytes alone. The addition of 1  $\mu$ g of the glycoprotein extract to  $10^6$  L1210 cells and  $10^8$  IgG-sensitised erythrocytes resulted in 73% inhibition of EA rosette formation.

Purified human IgG (Miles Laboratories, Elkhart, Indiana) was extensively absorbed with viable L1210 cells and an F(ab')<sub>2</sub> fraction prepared by pepsin digestion and Sephadex G-200 fractionation<sup>12</sup>. Purity of the intact and digested IgG was determined using SDS-polyacrylamide gel electrophoresis<sup>13</sup>. Cyanogen bromide-activated Sepharose 4B was coupled to either heat-aggregated human IgG, heat-aggregated F(ab')<sub>2</sub> human IgG, or keyhole limpet haemocyanin (KLH) as described previously<sup>6</sup>, and five columns containing 2 mg of coupled protein were prepared. Rabbit anti-human IgG (Cappel Laboratories, Downingtown, Pennsylvania) was added to one of the columns containing coupled aggregated human IgG, and rabbit anti-KLH was added to one of the KLH-coupled columns, so that two columns contained antibody complexed to antigen. The other columns contained only coupled KLH, aggregated human IgG or aggregated F(ab')<sub>2</sub> IgG. All columns were washed with phosphate-buffered saline (PBS) until the  $A_{280}$  in the eluate was equal to a blank control.

Equal amounts of radioactive glycoprotein extract in PBS were applied to each column and after a 60-min incubation at 23 °C the columns were washed with PBS until the c.p.m. in the eluates were equal to background. The columns and washes were counted and the percentage c.p.m. bound was calculated (Table 1). Those columns containing Sepharose 4B coupled to IgG with an intact Fc region bound between 35–44% of the labelled preparation, whereas the F(ab')<sub>2</sub> IgG and KLH columns bound only 2.8% and 4.4%, respectively. Elution of the columns with 0.1 M citrate buffer (pH 3.2) containing 0.5 M NaCl removed most of the radioactive material which was bound to the columns that contained an intact Fc region (Table 1).

The citrate eluates were analysed using SDS-polyacrylamide gel electrophoresis (Fig. 1). No distinct components were detected in the citrate eluates from the F(ab')<sub>2</sub> IgG-coupled or the KLH-coupled columns. Three distinct peaks with apparent molecular weights of 65,000, 45,000 and 28,000 (designated FI, FII and FIII) were found in the eluate from the aggregated IgG-coupled column (Fig. 1). An identical pattern was observed when non-aggregated IgG was coupled to Sepharose 4B. The citrate eluates from the columns containing immune complexes (IgG-anti-IgG or KLH-anti-KLH) revealed the same three peaks and an additional peak (designated peak A) with an apparent molecular weight of 125,000 (Fig. 1). The possibility that peak A represents a gel artefact due to overloading with IgG eluted from the complex columns was discounted by the fact that only a faint Coomassie blue-positive IgG band was present on the gels. Furthermore, gels loaded with one tenth the radioactive material revealed no IgG staining band, but the continued presence of peak A.

Peak A, FI, FII and FIII were purified by electroelution from polyacrylamide gels<sup>14</sup> and each fraction contained less than 8%

**Fig. 1** Analyses of the SDS-polyacrylamide gel electrophoreses of the citrate eluates derived from Sepharose 4B columns coupled to aggregated human IgG to which anti-human IgG had been added (—), or to aggregated human IgG alone (---). The radioactive samples, in non-reducing conditions, were applied to parallel 7.5% acrylamide gels. Electrophoreses were carried out in non-reducing conditions to maintain the Fc binding properties of the proteins which were subsequently purified from the gels by electroelution. The citrate eluate from the KLH-coupled column, to which anti-KLH had been added, revealed an identical profile to the aggregated IgG-anti-IgG column. The citrate eluate from a non-aggregated IgG-coupled column had the same pattern as the aggregated IgG-coupled column. Peak A, which was demonstrated only in the citrate eluate of columns containing immune complexes, migrates in front of IgG and has an apparent molecular weight of 125,000. FI, FII, and FIII, with apparent molecular weights of 65,000, 45,000 and 28,000, were found in the citrate eluates from all columns that contained an intact Fc region. The citrate eluates from the F(ab')<sub>2</sub> IgG-coupled and KLH-coupled columns revealed no distinct peaks.

cross contamination from the other fractions. FI, FII and FIII revealed no change in molecular weight after reduction and alkylation. Reduction and alkylation of peak A resulted in the appearance of two radioactive peaks with apparent molecular weights of 74,000 and 60,000.

The ability of non-aggregated mouse myeloma proteins of different IgG subclasses to bind to intact L1210 cells was determined by indirect immunofluorescence. As judged by the intensity of the fluorescence, Table 2 shows that L1210 binds IgG preparations in the following order: human IgG = mouse IgG2a > mouse IgG1 > mouse IgG2b. Affinity columns of Sepharose 4B coupled to these same proteins were prepared and the percentage labelled peak A, FI, FII, and FIII bound by these columns determined (Table 2). All isolated glycoproteins bound better to human IgG or mouse IgG2a than to mouse IgG1 or IgG2b.

**Table 1** Binding of <sup>125</sup>I-labelled glycoprotein extract to Sepharose 4B columns coupled to different IgG preparations

Buffer	Aggregated F(ab') <sub>2</sub> IgG	Aggregated IgG	% c.p.m. bound Aggregated IgG + anti-IgG	KLH	KLH + anti-KLH
PBS, 0.01 M (pH 7.2)	2.8	35.7	44.1	4.4	42.7
Citrate, 0.1 M NaCl, 0.5 M (pH 3.2)	1.6	8.4	6.7	4.2	10.1

Equal amounts of radioactive glycoprotein extract in PBS were applied to the columns. After extensive washing, so that the counts in the eluate equalled background, the columns and washes were counted and the percentage of the applied c.p.m. bound was calculated. The columns were then eluted with citrate buffer and the percentage of applied c.p.m. remaining on the columns was calculated.

**Table 2** Correlation of IgG subclass binding of intact L1210 cells and isolated Fc binding proteins

Sample	Human IgG	Mouse myeloma proteins		
		IgG1	IgG2a	IgG2b
L1210 Cells	++++	++	++++	+
Peak A	74.8	32.8	61.2	26.2
FI	59.6	40.8	63.8	32.6
FII	66.6	26.9	64.9	35.6
FIII	45.5	30.4	46.6	30.0

L1210 cells were incubated with either human IgG or one of the mouse myeloma proteins, washed, and then stained with the appropriate fluorescein conjugate (anti-human IgG or anti-mouse Ig). The intensity of the fluorescence was graded from + (barely visible) to ++++ (most intense). Peak A, FI, FII and FIII were passed over Sepharose 4B columns to which equal amounts of human IgG or one of the myeloma proteins had been coupled. The columns were washed with PBS until the c.p.m. in the eluates were equal to background. The numbers refer to the percentage of counts bound by each column.

These experiments indicate that four proteins which bind to the Fc region of IgG can be isolated from the glycoprotein extract of the plasma membranes of L1210. These proteins exhibit the same IgG subclass affinity as the intact cell, indicating their relationship to the cell's Fc receptors; however, their relationship to one another has not been determined. FI, FII, and FIII are composed of single polypeptide chains of similar amino acid composition, yet they differ considerably in their apparent molecular weights. Preliminary data suggest that the apparent differences may be due to either differences in the carbohydrate moieties of the molecules, or aggregation which is induced during the isolation procedure on SDS gels<sup>15</sup>. The smaller proteins may also represent degradation products of a larger Fc receptor. We consider this possibility less likely, since the addition of proteolytic inhibitors throughout the isolation procedure does not alter the results, and the isolated molecules still retain their Fc-binding properties.

Frøland *et al.*<sup>4</sup> have presented data which suggest that the cells that form EA rosettes and those that bind aggregated IgG may be separate. Our data may provide a molecular basis for explaining these observations. The Fc binding proteins (FI, FII and FIII) isolated from L1210 bind to monomer or heat-aggregated IgG, whereas peak A seems to have specificity for IgG complexed to antigen. Thus, the ability to form rosettes with IgG-coated erythrocytes could depend on the possession of an Fc receptor which binds IgG antibody complexed to antigen, and this receptor may be distinct from the Fc receptor which binds IgG that is not complexed to antigen. It is also possible that the smaller Fc binding molecules which we have isolated may be related to each other and may be derived from a larger, complex Fc receptor. The different binding specificities exhibited by an individual cell could then be accounted for by the way in which these molecules are arranged or linked to one another on the cell's surface.

## Antagonism of antigen-induced contraction of guinea pig and human airways

EXPOSURE of isolated sensitised guinea pig or human airway tissue to specific antigen produces a rapid and prolonged contraction which has been studied as a model of asthmatic bronchospasm. This response is thought to be mediated by endogenous chemicals released from airway mast cells, since antigen treatment of sensitised guinea pig or human pulmonary tissue results in the elaboration of several substances, including histamine and slow reacting substance of anaphylaxis (SRS-A), which can contract airway smooth muscle. The few attempts at investigation of which mediators are responsible for the airways response have led to contradictory conclusions. Schild *et al.*<sup>1</sup> reported that antihistamines significantly (but not completely) antagonised antigen-induced contraction of bronchi from an asthmatic patient. Sheard and Blair<sup>2</sup>, however, demonstrated that antihistamines had no effect on the contraction of human bronchial strips studied in the presence of antigen-challenged, passively-sensitised human lung. They suggested, without direct evidence, that the contractile response of the bronchial strip was the result of SRS-A release. At present, therefore, the roles of histamine and SRS-A in the airway response to antigen have not been defined. We have investigated the effects of diphenhydramine, a histamine H<sub>1</sub> antagonist, and FPL 55712 (ref. 3), an SRS-A antagonist, on the response of sensitised guinea pig and human airways to antigen and report that pretreatment with either alone modifies the airway response in a characteristic fashion, and that together, they effectively inhibit antigen-induced airway constriction.

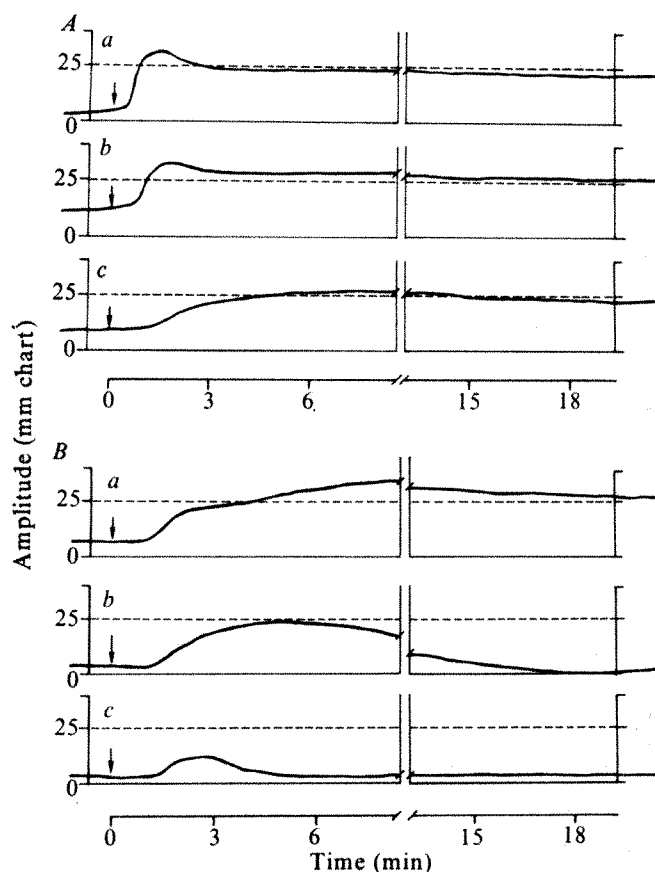

Tracheas of male Hartley guinea pigs passively sensitised with rabbit anti-dog albumin were cut into rings which were tied together to form a chain and placed in an organ bath containing Tyrode's solution. Three chains of three rings each were constructed from each trachea and were studied simultaneously. Human bronchial tissue obtained from patients undergoing surgical procedures was sensitised by incubating with serum from a ragweed allergic subject. Circumferential bronchial strips, studied in duplicate or triplicate, were suspended in an organ bath containing Krebs-Henseleit solution. Isometric airway tissue contractions were recorded.

Exposure of either tissue to specific antigen resulted in a rapid contraction equivalent in amplitude to approximately 40-100% of maximum contraction. Unsensitised tissue did not respond. Although the amplitude of the antigen-induced contraction varied considerably from day to day, within each experiment the responses of the chains or strips from one smooth muscle preparation were approximately equal. The duration of the response, ranging from 30 to 150 min, was proportional to the amplitude and was essentially unaffected by repeated washings.

Pretreatment of guinea pig or human airway tissue with diphenhydramine delayed the onset of the response to antigen and decreased the rate of development of the contraction (Fig. 1A). Within each experiment, the effects of diphenhydramine were dose dependent, with effects noted at concentrations as low as 10<sup>-7</sup> M. Pretreatment with doses of diphenhydramine as high as 10<sup>-4</sup> M, however, did not significantly decrease the amplitude or duration of the antigen-induced contraction. Higher concentrations caused no specific effects, but even 10<sup>-3</sup> M diphenhydramine had no effect when added after the airway response to antigen had developed.

Pretreatment with FPL 55712 in doses up to 5 × 10<sup>6</sup> g ml<sup>-1</sup> did not significantly alter the initial phase of the airways

response to antigen but produced a dose-related decrease in amplitude and duration of the prolonged phase of the response (Fig. 1*B,b*). Higher concentrations of FPL 55712, in addition to further depressing the amplitude and duration of the prolonged phase, inhibited to some extent the initial phase of the antigen-induced contraction

**Fig. 1** Effect of, *A*, diphenhydramine, and *B*, FPL 55712, on the response of sensitized guinea pig trachea to antigen. *A*, Male Hartley guinea pigs (300–350 g) were passively sensitized by injecting 0.2 ml rabbit anti-dog albumin (Cappel Laboratories, Cochranville, Pennsylvania, 2 mg antibody protein ml<sup>-1</sup>) intraperitoneally (i.p.) 12–16 h before use. After the animals were killed (pentobarbital, 90 mg kg<sup>-1</sup> i.p.), the tracheas were removed and cut into rings 2 mm wide. These were tied together to form a chain and placed in a 37 °C organ bath containing Tyrode's solution bubbled with 95% O<sub>2</sub>–5% CO<sub>2</sub>. Three chains of three rings each were constructed from each trachea and were studied simultaneously. Airway tissue contractions were measured with Grass FT03C force-displacement transducers and recorded on a Grass Model 7 polygraph. After the initial tension was adjusted (1 g), the tissue was washed and treated with several doses of methacholine (2.5 × 10<sup>-6</sup> M), until a consistent response was established. This dose of methacholine produced a contraction of the guinea pig airway tissue approximately equivalent to 75% of maximum, defined in our experiments as the response to 10<sup>-3</sup> M methacholine. Amplifier gain was adjusted to give equivalent recorded contraction amplitude for each chain to the test dose of methacholine. The tissue was then washed and incubated for 10 min with diphenhydramine (*b*, 10<sup>-3</sup> M; *c*, 10<sup>-5</sup> M). *a*, Untreated control tissue. Dog albumin (10<sup>-6</sup> g ml<sup>-1</sup>) was added to each bath at the arrow. Control response to antigen was equivalent to 56% maximum contraction. Diphenhydramine produced a delay in onset of response to antigen (100% greater than control for 10<sup>-7</sup> M, 200% for 10<sup>-5</sup> M) and a decrease in initial rate of contraction. Duration of response (120 min) was unaffected. *B*, Tissue preparation as *A*, except that tracheal rings were incubated with FPL 55712 for 10 min (*b*, 2 × 10<sup>-6</sup> g ml<sup>-1</sup>; *c*, 2 × 10<sup>-5</sup> g ml<sup>-1</sup>). *a*, Control response of untreated tissue. Dog albumin (10<sup>-6</sup> g ml<sup>-1</sup>) was added to each of the baths at the arrow. Control response to antigen was equivalent to 60% maximum contraction. In contrast to antihistamine (*A*), FPL 55712 decreased duration of response to antigen by 85% (2 × 10<sup>-6</sup> g ml<sup>-1</sup>) and 95% (2 × 10<sup>-5</sup> g ml<sup>-1</sup>). Control duration was 110 min. Decrease in amplitude of early phase of response (*c*) was a result of antihistamine-like properties of FPL 55712.

**Fig. 2** Effect of diphenhydramine in combination with FPL 55712 on sensitized human airways response to antigen. Human bronchial tissue, obtained from a patient undergoing surgery, was passively sensitized by incubating overnight at 25 °C with serum from a ragweed allergic subject (1:40 dilution in a balanced salt solution). Serial circumferential subsegmental bronchial strips were suspended in organ baths containing Krebs–Henseleit solution, bubbled with 95% O<sub>2</sub>–5% CO<sub>2</sub> and maintained at 37 °C. Tissue contractions were measured as described in Fig. 1. After a consistent response to methacholine (2.5 × 10<sup>-6</sup> M) was established and amplifier gain was adjusted to give equivalent recorded contractions to the test dose of methacholine, the tissue was washed and the bronchial strip depicted in *b* was incubated with diphenhydramine (10<sup>-3</sup> M) combined with FPL 55712 (10<sup>-5</sup> g ml<sup>-1</sup>) for 10 min. *a*, Control response of untreated tissue. Antigen E (5 × 10<sup>-7</sup> g ml<sup>-1</sup>) was added to each of the baths at the arrow. Control response to antigen was equivalent to 84% maximum contraction. Combination of antagonists produced delay in onset of response, decrease in amplitude of early and prolonged phases of contraction and a decrease in duration. Control response duration was 150 min.

(Fig. 1*B,c*). This effect is attributable to the reported<sup>3,4</sup> antihistamine activity of FPL 55712. FPL 55712 added during the prolonged phase of antigen-induced contraction of guinea pig or human airway tissue reversed the response, the dose required being somewhat higher than that effective in pretreatment.

Diphenhydramine (10<sup>-3</sup> M) in combination with FPL 55712 (10<sup>-5</sup> g ml<sup>-1</sup>) administered before the antigen regularly reduced both the amplitude and duration of the antigen-induced contraction to less than 30% of control, with complete blockade frequently being observed. Figure 2 shows the effect of pretreatment with both diphenhydramine and FPL 55712 on the response of human bronchial tissue to antigen. The extent of inhibition by this combination of antagonists depended on the relative amplitude of the contraction.

These data represent the first clear evidence that both histamine and SRS-A contribute to antigen-induced contraction of sensitized airway tissue and have important implications for the pharmacological control of human asthma. Histamine is primarily involved in the early phase of the response, commencing 1–2 min following the administration of antigen. This is the period most frequently examined in screening drugs by antigen broncho-provocation in man. The effect of histamine was particularly obvious in the pattern of contraction of guinea pig trachea, where the response frequently showed two amplitude maxima, one occurring within 3 min of antigen administration and the other occurring after about 10 min. Pretreatment with diphenhydramine selectively abolished the early contraction maximum without altering the amplitude or duration of the later phase of the response. Maximal inhibition of the early phase of the response required about 10<sup>-3</sup> M diphenhydramine. From data on the antagonism of exogenous histamine it seems that the mean effective tissue concentration of histamine in the region of the smooth muscle cells must be quite high, probably approaching 10<sup>-3</sup> M.

SRS-A seems to contribute to the later, prolonged phase of the airway response to the antigen, since this phase

is effectively antagonised by FPL 55712 but not by diphenhydramine. The dosages of FPL 55712 required to produce a maximal effect were considerably higher than those reported by Augstein<sup>3</sup> or Orange<sup>4</sup> to inhibit SRS-A-induced contraction of guinea pig ileum. This is not surprising since, like that of histamine, the tissue concentration of SRS-A following antigen treatment must be many orders of magnitude higher than that achieved by the addition of exogenous SRS-A to an organ bath. Whether other mediators contribute to the response or modulate the airways reactions to histamine or SRS-A is not yet clear, but it seems evident that pharmacological control of human airways reactions *in vivo* will require either a drug which inhibits the release of multiple mediators or a combination of specific antagonists.

We thank Deborah Wolff for technical assistance. FPL 55712 was kindly provided by Fisons Ltd. This work was supported by grants from the United States National Institutes of Health.

## An octopaminergic neurone modulates neuromuscular transmission in the locust

OCTOPAMINE, a biogenic amine, occurs widely in the nervous systems of vertebrates and invertebrates<sup>1-3</sup>. It has been found in single neurones in the central nervous system of the marine mollusc, *Aplysia*<sup>4</sup> and also in peripheral neurosecretory neurones in the lobster<sup>5,6</sup> from which a calcium-dependent release of octopamine has been demonstrated<sup>7,8</sup>. Specific octopamine receptors<sup>9</sup> and octopamine activated adenylate cyclases<sup>10</sup> have also been found in invertebrate nervous tissue. This has led to the suggestion of a neurotransmitter role for octopamine in invertebrates<sup>1,3</sup>. In the absence, however, of an example in which the effect of stimulating an identified octopamine containing neurone on its identified target or end organ is known, the true function of octopamine remains obscure. This paper aims to demonstrate that octopamine is the neurotransmitter of a single identified neurone in the locust *Schistocerca americana gregaria*. This neurone, which is shown to contain octopamine, innervates a muscle where it functions as a neuromodulator by potentiating the synaptic potential and tension produced by an identified motoneurone. That this function is mediated by the release of octopamine on stimulation is supported by the action of exogenously applied octopamine.

The extensor-tibiae muscle of the locust hind leg is a large and powerful muscle used in walking, kicking and jumping. It is innervated by three motoneurones<sup>11-13</sup> whose axons are contained in the extensor-tibiae nerve. They are the fast and the slow extensor motoneurones (FETi and SETi) and an inhibitory motoneurone which innervates many muscles and has, therefore, been called the common

inhibitor (CI). These neurones are paired and so there are six identified motoneurones controlling the paired (left and right) extensor muscles. Their cell bodies lie in known positions in the metathoracic ganglion (Fig. 1a). The muscle also receives a fourth axon<sup>14</sup> belonging to a single unpaired

**Fig. 1** The experimental arrangement and the identification of DUMETi. *a*, Recording (R) and stimulating (S) sites referred to here and in Fig. 3. ●, Positions of the neurone cell bodies in the locust metathoracic ganglion which have axons in the extensor tibiae nerve. Independent stimulation of each axon in the extensor nerve was achieved as follows. The DUM axon was stimulated either by passing current into the soma of DUMETi (S3) or by antidromic stimulation of the left extensor nerve (S1). Selective stimulation of the axon of the slow extensor motoneurone (SETi) in a branch of nerve 3 (S2) which contains both its axon and that of the common inhibitory motoneurone (CI) is achieved by the relatively larger diameter of the former which gives it a lower threshold to extracellular stimulation. The common inhibitory motoneurone was stimulated in a branch of nerve 3 (S4) which contains its axon but lacks other axons which project to the extensor muscle. Muscle tension is monitored almost isometrically with a tension transducer placed on the muscle tendon (R4). *b*, Spikes initiated in the soma of DUMETi (R1/S3) are transmitted 1:1 to both left and right extensor nerves. This distinguishes the DUMETi neurone soma from those of other DUM cells. *c*, The oscilloscope is triggered several times by spikes recorded in the soma of DUMETi, note that spikes on the left (R2) and right (R3) axons superimpose. The difference in absolute latency between spikes recorded left and right is caused by a difference in the distance from the soma of sites R2 and R3. *d*, The soma spike can be initiated antidromically by stimulating either left or right extensor nerves. If the soma is hyperpolarised, the active soma spike fails to initiate in response to antidromic stimulation (R1, lower trace). The smaller positive potential seen in the soma is a recording of the axon spike conducted passively from its site of initiation.

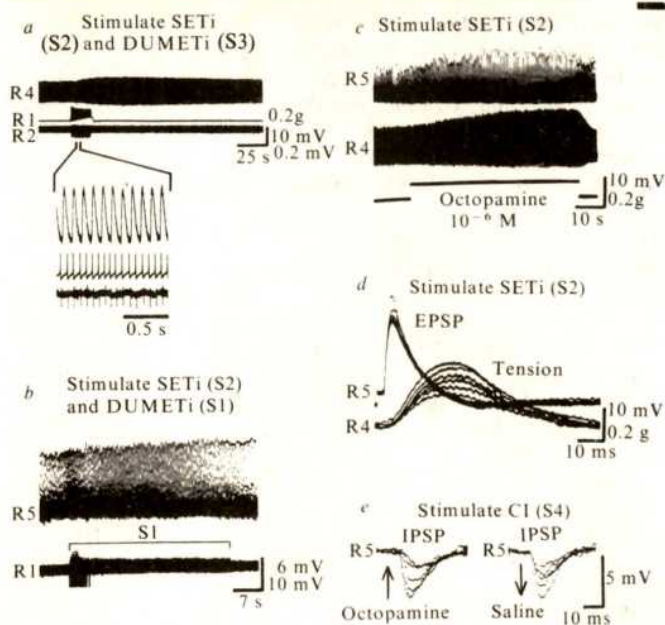

neurone with its cell body among a group of similar unpaired neurones in the dorso-medial region of the metathoracic ganglion<sup>15,16</sup>. They are called Dorsal Unpaired Median or DUM neurones and the one which innervates the extensor-tibiae muscle is known as DUMETi<sup>14</sup>.

The DUM cells stain selectively with the dye neutral red (Fig. 2), a dye known to stain monoamine-containing neurones in the leech<sup>17</sup> and lobster nervous systems<sup>5,6</sup>. This finding, together with the observation that tissue removed from the dorsal part of the locust metathoracic ganglion, possibly containing DUMETi, is capable of octopamine synthesis from tyrosine<sup>18</sup>, directed our attention towards the identification of a biogenic amine, possibly octopamine, as a neurotransmitter for DUMETi. We identified the DUMETi neurone by intracellular recording (Fig. 1 b-e) in 50 animals. The soma was removed, cleaned of adhering pigment cells and other tissue and transferred to a microtube containing 10  $\mu$ l of 0.01M formic acid. Five assays were performed on pools each containing 10 identified DUMETi cell bodies. Octopamine was assayed by a modification (P.D.E. in preparation) of the standard radio-enzymatic assay<sup>19</sup> which detected as little as 10 pg of DL-octopamine. The identity of the assay products was checked by several chromatographic and electrophoretic techniques<sup>6</sup>. The mean amount of octopamine found per DUMETi soma ( $\pm$ s.e.m.) was  $0.10 \pm 0.02$  pmol. Control assays performed on pools of up to 37 fast extensor motoneurone cell bodies gave no detectable octopamine. The minimum concentration ratio between the two neuronal types is therefore 800:1. Octopamine was also detected in pieces of extensor nerve which contained the axon of DUMETi but was undetectable in pieces of the same nerve which on physiological evidence were known to contain only the axons of the slow extensor and common inhibitor motoneurons. Of the neurones innervating the extensor muscle, therefore, only DUMETi contains octopamine. Octopamine is about four times more concentrated in the axon of DUMETi than in its soma.

We were first alerted to the possibility that DUMETi is

**Fig. 2** A dorsal view of a locust metathoracic ganglion showing the medial group of cell bodies stained with the dye neutral red ( $0.01 \text{ mg ml}^{-1}$  in isotonic locust saline for 3 h at room temperature). The group contains two quite distinct size classes, large (L) and small (S) cells. The soma of the DUMETi neurone is a member of the group of large cells. The organisation of the group is variable, the soma of DUMETi can be found anywhere among the group of large cells. Compare ganglion outline with Fig. 1a. A, Anterior; P, posterior. Scale bar, 100  $\mu$ m.

**Fig. 3** a, The effect of stimulating DUMETi on extensor muscle tension generated by the slow extensor motoneurone. The time base is expanded below to show the individual twitches of the muscle (R4), the soma spikes (R1) and axon spikes (R2) of DUMETi. The slow motoneurone was stimulated at 10 Hz. Note the slow potentiation and long lasting effect of DUMETi on tension. b, The effect of stimulating DUMETi on EPSP amplitude (R5). DUMETi is stimulated antidromically (S1) at 20 Hz. At this frequency the soma spikes are unable to follow 1:1 and fail to initiate at all after the first few seconds of stimulation. A few soma spikes can be seen during the initial seconds of stimulation (R1); subsequently only the smaller axon spike is recorded in the soma. c, The effect of  $10^{-6}$  M DL-octopamine in saline on the EPSP (R5) and tension (R4) generated by stimulating the slow motoneurone (S2). d, The oscilloscope is triggered by the stimulus delivered to the slow motoneurone (S2). Each EPSP (R5) produces a response in the tension transducer (R4). A series of six triggered sweeps about 5 s apart starting at the arrival of octopamine are shown. They show a graded increase in the EPSP amplitude and a graded increase in the tension. e, The effect of  $10^{-6}$  M octopamine in saline on the amplitude of IPSP (R5) elicited by stimulating the common inhibitory motoneurone. On the left a graded decline in the IPSP amplitude following superfusion with octopamine and on the right there is a graded recovery of the IPSP amplitude when the octopamine solution is replaced with saline. The oscilloscope is triggered by the stimulus delivered to the common inhibitor axon (S4) and five sweeps about 5 s apart are superimposed.

involved in synaptic modulation by our observation that the tension generated by the slow extensor motoneurone was potentiated by DUMETi stimulation (Fig. 3a) (M.O. and P.D.E. in preparation). The only mechanical effect of stimulating DUMETi alone is a small decrease in basal tonus. Exogenously applied octopamine enhances the tension evoked in the extensor muscle by the slow motoneurone (Fig. 3c) and this effect is blocked by the  $\alpha$ -adrenergic blocking agent, phentolamine. The increase in tension ( $<30\%$ ) is accompanied by a facilitation of the EPSP evoked by the slow motoneurone (Fig. 3b-d). In contrast, the IPSP elicited by stimulating the common inhibitory motoneurone is depressed by low concentrations of octopamine (Fig. 3e). These effects have a prolonged time course of many seconds. We could detect no effect of octopamine on the response of the muscle to stimulating the fast motoneurone.

We do not yet know the site of action or the mechanism of the synaptic modulation by octopamine. Octopamine could act on the postsynaptic muscle membrane or on the presynaptic terminals of the slow extensor and common inhibitory motoneurons and several mechanisms could mediate the effects shown here. Our demonstration, however, that octopamine can enhance excitation and depress

inhibitory neuromuscular synaptic transmission supports the growing evidence that amines have widespread modulatory roles<sup>7,20-22</sup>.

## Magnetic ferrofluids for preparation of magnetic polymers and their application in affinity chromatography

THE use of magnetic polymers as supports for biological molecules has created much interest<sup>1-5</sup>. The inherent advantages of such preparations are, in particular, the ease of recovery of these polymers by applying a magnetic field. Thus, when used as supports for immobilised enzymes, their easy retrieval from liquors containing colloids or undissolved solids should be of great practical value<sup>1-3</sup>. Magnetic polymers have recently been tested as an alternative to conventional radioimmunoassay technique, obviating the need for vertical rotation and for the time-consuming, multiple centrifugations required with conventional solid phase procedures<sup>1-5</sup>. In the established techniques for producing magnetic polymer particles, the attachment of the biomolecules had to follow the preparation of the specific magnetic material; furthermore most of these preparations have been non-porous, exhibiting rather poor capacity. We describe here a novel and general procedure using magnetic fluids which allows 'post-magnetisation' of polymers already substituted with biological molecules. The properties of such preparations have been tested primarily as affinity chromatography gels. These preparations showed unaltered biospecificity when applied in general ligand-affinity chromatography studies. The simplified separation possible due to the magnetic properties of the gels eliminates the usual centrifugation and column chromatography steps. The procedure of 'post-magnetisation' seems to be suitable for different polymer particles, both unsubstituted gels and those carrying immobilised ligands as affinity adsorbents or enzymes.

The basic new principle in the procedure described here is the use of magnetic fluids. These can be characterised as fluids consisting of ultramicroscopic particles (~100 Å) of oxides. These are stabilised by a coating, typically 25-Å thick, preventing their sticking together in a magnetic field. Random collisions (Brownian motion) with the carrier

liquid's molecules keep the particles in colloidal suspension and are additionally stabilised by physicochemical means. In the following, ferrofluids, that is, those containing ferrite particles, have been used and with either water or hydrocarbon as the carrier. They behave like true homogeneous fluids, yet are highly susceptible to magnetic fields.

One gram of moist 5'-AMP- (or 2', 5'-ADP) -Sephacrose 4B (Pharmacia) which was previously swollen in 0.1 M sodium phosphate buffer pH 7.5, and washed with H<sub>2</sub>O was packed in a column. Subsequently 6.5 ml of ferrofluid (base, H<sub>2</sub>O; magnetic saturation, 200 G; trademark A05, from Ferrofluidics Corporation, Burlington, Mass.) were pumped through the column and cycled for 4 h at a flow rate of 50 ml h<sup>-1</sup> (usually at room temperature). After washing with 1 l of H<sub>2</sub>O, on glass filter, incubation overnight at 4 °C with 100 mg of bovine serum albumin in 0.1 M Tris-HCl buffer pH 7.6, 5 mM in EDTA and 1 mM 2-mercaptoethanol was carried out, followed by washing with 200 ml 1 M NaCl and 200 ml of the same buffer. The dark brown gel beads were then magnetic and ready for use (Some enzymes tested are slowly inactivated, for reasons at present not yet definitely established, unless albumin treatment is carried out.)

When applying ferrofluids with a hydrocarbon as a base, an alternative procedure also involving albumin treatment was applied. The hydrocarbon-based ferrofluid (hydrocarbon; trademark HO1, magnetic saturation: 200 G) was circulated through the bed containing beads previously treated with solutions of gradually changing composition going from water to acetone. After the ferrofluid treatment the beads were filtered on a glass filter and washed with acetone. This was followed by successive washing with different solvent mixtures in the sequence: acetone, acetone-cyclohexane, cyclohexane, cyclohexane-acetone, acetone, water and finally buffer. To further increase the magnetic properties of the latter preparations they were treated once more before the final acetone washing. No differences in the affinity behaviour of the two types of preparations were noticed.

Whether the ferrite particles simply adsorb to the gel or precipitate out in the interior of the beads remains to be established. (In this context it should be noted that entrapment of ferrofluid within the lattice of polyacrylamide can easily be accomplished.) In any case, the magnetic properties of the gel remain unchanged after extensive washing with buffer (even washing with, for example, ethanol or 40% ethylene glycol did not remove the ferrite particles) and repeated use in magnetic fields; they are strong enough to allow rapid sedimentation even when applying weak permanent magnets.

To establish the usefulness of the magnetic Sepharose beads for affinity chromatography, we had to establish whether the biospecificity of the immobilised ligands remained unchanged, and to investigate the capacity of the gels. To study the former aspect, beef heart lactate dehydrogenase was chosen as model enzyme and applied to magnetised 5'-AMP-Sepharose 4B. As expected it bound to the 5'-AMP-gel, known to be specific for NAD<sup>+</sup>-dependent enzymes, and could subsequently be eluted quantitatively with 1 mM NADH (Fig. 1a). In contrast the NADP<sup>+</sup>-dependent enzyme 6-phosphogluconate dehydrogenase, chosen as reference, showed no affinity for the gel, which is in accord with previous findings using non-magnetised preparations of this general ligand<sup>6</sup>. Conversely, lactate dehydrogenase would not bind to 2', 5'-ADP, known to be specific for NADP<sup>+</sup>-dependent enzymes, in contrast to 6-phosphogluconate dehydrogenase, which bound and could be subsequently eluted with 1 mM NADPH (Fig. 1b).

To further investigate the usefulness of the magnetic affinity material prepared, isozyme separation of horse liver alcohol dehydrogenase was attempted. On applying a

**Fig. 1** *a*, To 0.4 g of moist magnetic 5'-AMP-Sepharose 4B (ferrofluid  $H_2O$ ) were added 118 units (0.36 mg) of lactate dehydrogenase (from beef heart) or 4.5 units of phosphogluconate dehydrogenase (0.8 mg) from yeast in 2 ml of 0.1 M Tris-HCl, pH 7.6 containing 5 mM EDTA and 1 mM 2-mercaptoethanol. After incubation for 30 min on a rocking table (alternatively the gel could be kept suspended through a magnet kept at the outside of a rotating glass tube), the gel was settled in a beaker by applying at the outside a cylinder-formed permanent magnet with a pull of approximately 5 kg. After removal of the 'supernatant' from the gel (batch no. 1), the latter was washed 15 min in  $4 \times 10$  ml of the incubation buffer (batch nos 2-5). Elution of the affinity-bound enzyme was achieved by incubation for 15 min in 10 ml of 1 mM NADH in the buffer. All experimental manipulations were carried out at 4 °C and enzymes assayed as described earlier<sup>6</sup>; batch no. on the abscissa refers to the number of successive washings and elution carried out with one affinity gel preparation. *b*, To 0.4 g of moist magnetic 2',5'-ADP-Sepharose 4B (ferrofluid, hydrocarbon) were added, as above, either lactate dehydrogenase or 6-phosphogluconate dehydrogenase. The experimental procedures were as for (a) except for the use of 1 mM NADPH.

mixture of the three isozyme forms EE, ES, and SS to magnetised 5'-AMP-Sepharose 4B, we found that they would adsorb to the gel. Afterwards a pulse of  $NAD^+$  plus cholic acid eluted primarily the steroid active isozyme SS. With a subsequent application of NADH, the EE and ES forms were eluted, which is in analogy to previous findings<sup>7</sup>. It was found that the ratio of ethanol to steroid (5 $\beta$ -dihydrotestosterone) activity in the fractions eluted with  $NAD^+$  plus cholic acid showed, after only one batch treatment, the low value of 1.3; this compares with 1.1 found for completely pure SS isozyme. (The applied mixture had a ratio of 7.) Clearly the elution technique used previously, which leads to purification of the SS isozyme, is applicable also to the magnetic polymer particles<sup>8</sup>.

Finally, a magnetised 5'-AMP-Sepharose 4B preparation was used for the purification of horse liver alcohol dehydrogenase from crude extracts<sup>7</sup>. As shown in Table 1, alcohol dehydrogenase of high specific activity was obtained in one step. The enzyme was almost pure as judged from sodium dodecylsulphate-gel electrophoresis. The procedure com-

**Table 1** Purification of horse liver alcohol dehydrogenase by magnetic 'general ligand-affinity chromatography' in one step

Step	Specific activity (U mg <sup>-1</sup> )	Purification (n-fold)	Capacity (mg of protein per g moist gel)
Crude extract	0.08	1	
Magnetic 5'-AMP-Sepharose 4 B	1.70	21	0.7
5'-AMP-Sepharose 4B	1.98	25	1.5

A crude extract of horse liver was prepared as previously described<sup>7</sup> with a protein concentration of 46.4 mg ml<sup>-1</sup>. A large excess of protein (100-200 mg) in relation to 1 g of magnetic moist 5'-AMP (ferrofluid hydrocarbon)-Sepharose present in a beaker was applied. After incubation for 60 min on a rocking table, the gel was settled in a magnetic field and the 'supernatant' removed. Before elution of the affinity-bound enzyme, the gel was washed extensively with 0.1 M sodium phosphate buffer, pH 7.5 followed by a wash for 15 min in 0.1 mM  $NAD^+$  (4 ml) and the above buffer ( $3 \times 10$  ml). The enzyme was then eluted by addition to the gel of 3 ml of 0.1 mM  $NAD^+$  + 5 mM pyrazole in the above buffer (30 min, 4 °C). The lower set of values refers to a parallel run using identical amounts of non-magnetic affinity gel.

pared well with a blank run using non-magnetised 5'-AMP-Sepharose 4B, also in batch-fashion; only the capacity of the gel was diminished to about half. But its value of 0.7 mg of enzyme per g of moist gel is high when compared with some of the magnetic gels prepared in the beginning of this study following conventional approaches as entrapment of  $Fe_3O_4$  particles inside gels.

A further advantage of the use of magnetic polymers in affinity chromatography lies in the fact that it allows a rapid 'pick-up' of molecules from colloidal solutions or those containing cell debris. Such quick retrieval would be most difficult or impossible to accomplish by conventional purification methods. This advantage seems to be of particular value if a rapid isolation of labile enzymes or enzyme complexes after their liberation from the cell is required. It is likely that once the enzyme is affinity-adsorbed within the pores of a gel, it is more protected, for example, against proteolytic enzymes. To test the ease of enzyme isolation, the following model experiment was carried out: horse liver was quickly ground and immediately thereafter magnetic 5'-AMP-Sepharose beads were added to the homogenate. After incubation, the cell debris was decanted by keeping the gel particles at the bottom of the beaker through a permanent magnet placed at the outside. After several batch-washings, alcohol dehydrogenase was ready to be eluted in  $NAD^+$  plus pyrazole. Although the enzyme obtained showed lower specific activity (0.65 units mg<sup>-1</sup>) than that given in Table 1, it clearly demonstrates the potential of the procedure.

Thus the simple technique applied here for the 'post-magnetisation' of pre-formed polymers already substituted with ligands has been shown not to alter the affinity properties of the polymers tested. This technique has also been applied successfully to unsubstituted gels such as Sepharose 4B or Sepharose Cl 6B. In addition, magnetic enzyme-bearing polymers were prepared applying the procedure described. Using trypsin as model enzyme, magnetic Sepharose-trypsin preparations were obtained with equivalent specific activities relative to soluble enzyme, as found with normal Sepharose-coupled trypsin preparations. In a typical experiment 5 mg of trypsin (bovine pancreas, Sigma type III) were allowed to couple to 1 g of moist Sepharose 4B activated by the CNBr procedure<sup>9</sup>. After washing, the Sepharose-trypsin preparation was treated for 4 h at 4 °C with 6 ml of ferrofluid ( $H_2O$  as base) in analogous manner to the procedure given.

Alternatively, the Sepharose beads were first magnetised and then underwent CNBr activation and trypsin coupling.

The latter preparation showed higher specific activity (relative to soluble enzyme) compared with the former (30% compared with 20%) but was somewhat less magnetic.

It seems that the magnetisation procedure described here using magnetic fluids will be of general interest, since in addition these fluids are also relatively inexpensive. We have demonstrated here the usefulness of the procedure for the preparation of suitable magnetic-affinity chromatography systems and for the preparation of magnetic enzyme-bearing polymers, the latter with potential in the area of enzyme technology. One can envisage other areas in which similarly prepared magnetic biomolecule-polymer complexes may find application, for instance as components of immunoassay systems; similarly magnetic carrier systems for 'targeting of drugs' could be designed carrying drugs, enzymes or other molecules of therapeutic value, which through a magnetic field can be brought to the desired site of action. In contrast to previous methods of preparing magnetic particles whereby in order to obtain the required magnetic properties one is forced into a choice of particular polymer, magnetic particle or procedure (often at the expense of other desired properties as porosity), such considerations are not involved in the simple procedure given here.

We thank Mr Fritjof Karlén-Svensson and Miss Ulla Jeppsson for technical assistance and Drs Ann-Christin Koch-Schmidt and Bengt Danielsson for valuable help and discussions.

## Differential labelling of $\alpha$ and $\beta$ -noradrenergic receptors in calf cerebellum membranes with $^3\text{H}$ -adrenaline

$\beta$ -NORADRENERGIC receptor detection with radiolabelled catecholamines has been hampered by binding of catecholamines to other sites<sup>1,2</sup>. Lefkowitz and Williams<sup>3</sup> described binding of a synthetic catecholamine  $^3\text{H}$ -hydroxybenzylisoprenaline to  $\beta$ -noradrenergic receptors on frog red blood cell membranes. Using procedures to prevent metabolism and nonspecific binding, we identified binding of  $^3\text{H}$ -adrenaline to  $\alpha$ -noradrenergic receptor sites in brain membranes<sup>4,5</sup>. We report here the labelling of  $\beta$ -noradrenergic receptors in membranes of the calf cerebellum with  $^3\text{H}$ -adrenaline.

Homogenates of fresh or frozen calf cerebellar cortex were prepared as described previously<sup>4</sup>. Triplicate incubation tubes received 20  $\mu\text{l}$  of diluted  $^3\text{H}$ -adrenaline (DL-7,  $^3\text{H}$ (N)-epinephrine L-bitartrate, 11 Ci mmol<sup>-1</sup>, New England Nuclear) to give a final concentration of 10 nM  $^3\text{H}$ -adrenaline, 10  $\mu\text{l}$  of various concentrations of drugs, 20  $\mu\text{l}$  of a solution containing 50 mM pyrocatechol, 5 mM disodium EDTA and 0.5 mM dithiothreitol, and 0.94 ml of tissue suspension. In  $\beta$ -receptor binding experiments,  $\alpha$ -receptor binding was eliminated by the inclusion of 1.0  $\mu\text{M}$  phentolamine in incubation solutions. Conversely, in  $\alpha$ -receptor binding experiments, 1.0  $\mu\text{M}$  ( $\pm$ )-propranolol was included to abolish  $\beta$ -receptor binding of  $^3\text{H}$ -adrenaline.  $^3\text{H}$ -Adrenaline and all other drugs were made up in 0.1%

ascorbic acid. The tubes were incubated at 25 °C for 60 min, and then rapidly filtered under vacuum through Whatman GF/B filters presoaked in 1 mM pyrocatechol. The filters were rinsed with 16 ml of ice-cold 50 mM Tris-HCl buffer containing 1 mM pyrocatechol and 0.1% ascorbic acid, and were subsequently counted by liquid scintillation spectrometry in 10 ml Formula 947 (New England Nuclear) at 37% efficiency.

Saturable or specific binding of  $^3\text{H}$ -adrenaline to  $\alpha$ -receptors was measured in the presence of 1.0  $\mu\text{M}$  ( $\pm$ )-propranolol, as the excess over blanks which included 1.0  $\mu\text{M}$  oxymetazoline. Saturable or specific  $\beta$ -receptor  $^3\text{H}$ -adrenaline binding was measured, in the presence of 1.0  $\mu\text{M}$  phentolamine, as the excess over blanks which included 1.0  $\mu\text{M}$  ( $\pm$ )-propranolol. Previous experiments have demonstrated that after incubation of  $^3\text{H}$ -adrenaline with calf brain membranes for 60 min at 25 °C in the conditions mentioned here, radioactivity eluted from the membrane pellet and radioactivity in the supernatant was essentially identical to cochromatographed stock  $^3\text{H}$ -adrenaline<sup>5</sup>.

In the presence of 1  $\mu\text{M}$  phentolamine, specific binding of  $^3\text{H}$ -adrenaline to calf cerebellar membranes was saturable (Fig. 1). Scatchard analysis revealed a single population of binding sites, with a dissociation constant ( $K_D$ ) of 31 nM. The specificity of  $^3\text{H}$ -adrenaline binding in the presence of 1  $\mu\text{M}$  phentolamine fulfilled characteristics expected of  $\beta$ -noradrenergic receptors. Of the principal catecholamines, ( $-$ )-isoprenaline was most potent in competing for binding ( $K_i=1.9$  nM), exceeding the potencies of ( $-$ )-adrenaline and ( $-$ )-noradrenaline by ten- and 100-fold respectively (Table 1). The 10-fold greater potency of adrenaline than of noradrenaline indicated that in calf cerebellar membranes,  $^3\text{H}$ -adrenaline binding was associated with  $\beta_2$  receptors. Binding of  $^3\text{H}$ -adrenaline in the presence of 1  $\mu\text{M}$  phentolamine was stereospecific,

**Fig. 1** Specific  $^3\text{H}$ -adrenaline binding to  $\alpha$ - and  $\beta$ -receptors as a function of increasing concentrations of  $^3\text{H}$ -adrenaline. Calf cerebellar homogenates (20 mg original wet weight of tissue) incubated for 60 min at 25 °C as described in the text, with various concentrations of  $^3\text{H}$ -adrenaline. *a*, Binding to  $\alpha$ -receptors, measured in the presence of 1.0  $\mu\text{M}$  ( $\pm$ )-propranolol. Specific binding was that displaceable by 1.0  $\mu\text{M}$  oxymetazoline. *b*, Binding to  $\beta$ -receptors, measured in the presence of 1.0  $\mu\text{M}$  phentolamine. Specific binding was that displaceable by 1.0  $\mu\text{M}$  ( $\pm$ )-propranolol. In each case, specific binding was defined as the difference between total and nonspecific. Points shown are those obtained in a single experiment, performed in triplicate, which was replicated three times. *Inset*. Scatchard plots, showing  $K_D$  values of 5 nM at  $\alpha$ -receptors, and 31 nM at  $\beta$ -receptors. Specific binding of  $^3\text{H}$ -adrenaline to  $\alpha$ -receptors at a concentration of 70 nM was not significantly different from that obtained at 40 nM  $^3\text{H}$ -adrenaline, and is not shown in the concentration-binding curve, but is included in the Scatchard plot.

with (–)-catecholamines being 30–150 times more potent than the corresponding (+)-catecholamines. Affinities of other  $\beta$ -agonists paralleled their known pharmacological potencies and affinities for sites labelled by radioactive  $\beta$ -antagonists<sup>6</sup>.  $\beta$ -Noradrenergic antagonists competed potently and stereospecifically, with (–)-propranolol and (–)-alprenolol displaying apparent  $K_i$  values of 2–3 nM. Dichloroisoprenaline, (–)-practolol and butoxamine, pharmacologically weaker  $\beta$ -antagonists<sup>7</sup> were comparably weaker in competing for binding of <sup>3</sup>H-adrenaline. At concentrations as high as 10  $\mu$ M, drugs active at  $\alpha$ -noradrenergic receptor sites failed to influence the binding of <sup>3</sup>H-adrenaline, in the presence of 1  $\mu$ M phentolamine.

In the presence of 1  $\mu$ M ( $\pm$ )-propranolol, <sup>3</sup>H-adrenaline seemed to bind selectively to  $\alpha$ -receptor sites on calf cerebellar membranes, as reported earlier with calf cerebral cortex<sup>4,5</sup> (Fig. 1, Table 1). In these conditions, the specific binding of <sup>3</sup>H-adrenaline was saturable with maximal binding occurring by 20 nM. Scatchard analysis indicated a single population of binding sites, with a  $K_D$  value of 5 nM, similar to that found in the cerebral cortex. Thus <sup>3</sup>H-adrenaline displayed about six times greater affinity for  $\alpha$ - than for  $\beta$ -receptors. The substrate specificity of <sup>3</sup>H-adrenaline binding in the presence of propranolol was as expected at  $\alpha$ -receptor sites, with (–)-noradrenaline almost 100 times more potent than (–)-isoprenaline. The most potent catecholamine at apparent  $\alpha$ -sites was (–)-adrenaline, with an affinity three times greater than (–)-noradrenaline. The  $\alpha$ -agonist clonidine, the partial agonists ergotamine and piperoxan, and the  $\alpha$ -antagonists phentolamine and WB-4101 were potent competitors for the binding of <sup>3</sup>H-adrenaline in the presence of propranolol, with apparent  $K_i$  values in the 1–20-nM range. In general, the affinities of  $\alpha$ -receptor agonists and antagonists in competing for <sup>3</sup>H-adrenaline binding in the cerebellum in the presence of propranolol closely matched their affinities in competing for  $\alpha$ -receptor binding by <sup>3</sup>H-adrenaline, <sup>3</sup>H-noradrenaline and <sup>3</sup>H-clonidine in calf cerebral cortex<sup>4,5</sup> and rat brain<sup>8,9</sup>. Specificity of the binding of <sup>3</sup>H-adrenaline to  $\alpha$ -receptors in the presence of propranolol was supported by the very weak influence of  $\beta$ -agonists and  $\beta$ -antagonists on this binding (Table 1).

Kinetic studies were carried out to establish that the binding of <sup>3</sup>H-adrenaline to both  $\alpha$ - and  $\beta$ -receptor components was reversible. Specific binding in the presence of propranolol showed the same characteristics of association and dissociation at 25 °C as in the calf cerebral cortex<sup>5</sup>. Dissociation was biphasic, with a  $t_{1/2}$  of about 1.5 min, slightly faster than in the cortex. Seventy to eighty per cent of specific binding was dissociated after 10 min. Association of <sup>3</sup>H-adrenaline to  $\beta$ -receptors (in the presence of phentolamine) was more rapid than to  $\alpha$ -receptors; equilibrium binding, attained in 15 min, remained stable for 2 h. A standard incubation time of 60 min was chosen to parallel conditions for measuring binding to  $\alpha$ -receptors. Dissociation caused by adding a large excess of propranolol was extremely rapid at 25 °C, with a  $t_{1/2}$  of about 20 s, and complete dissociation after 2 min.

In preliminary experiments, we failed to demonstrate binding of <sup>3</sup>H-adrenaline to  $\beta$ -receptor sites in several rat brain regions, or in non-cerebellar areas of the calf brain. The ability to label  $\beta$ -receptors with <sup>3</sup>H-adrenaline in calf cerebellum may be related to the greater density of  $\beta$ -noradrenergic receptors in this tissue detected by the binding of the  $\beta$ -antagonists, <sup>3</sup>H-dihydroalprenolol and <sup>125</sup>I-hydroxybenzylpindolol (ref. 10 and our unpublished work), and to the observation that  $\beta$ -receptor sites in calf cerebellum are of the  $\beta_2$  type, in which adrenaline is about 10 times more potent than noradrenaline.

Binding studies with a variety of neurotransmitter receptors in the brain have revealed distinct differences between interactions of agonists and antagonists<sup>8,11–15</sup>. Most studies of  $\beta$ -receptors in various tissues have used only a radiolabelled antagonist. Evaluation of important questions of receptor functioning, such as desensitisation, requires studies of the

Calf cerebellar cortex homogenates were incubated with 10 nM <sup>3</sup>H-adrenaline for 60 min at 25 °C, in the presence of 1.0  $\mu$ M ( $\pm$ )-propranolol for  $\alpha$ -receptor binding, or 1.0  $\mu$ M phentolamine for  $\beta$ -receptor binding, together with 3–6 concentrations of unlabelled drugs, using the standard assay conditions as described in the text.  $IC_{50}$  values were determined by log-probit analysis, and apparent  $K_i$  values calculated from the equation  $K_i = IC_{50}/(1 + [^3H\text{-adrenaline}]/K_D)$ . The  $K_D$  values used were 5 nM for  $\alpha$ -receptor binding, and 31 nM for  $\beta$ -receptor binding. Values given are means from 2 to 4 experiments, each conducted in triplicate, which varied less than 20%.

direct binding of radiolabelled agonists. It is also desirable to label receptors with naturally-occurring transmitters or transmitter analogues. Accordingly, labelling  $\beta$ -receptors with <sup>3</sup>H-adrenaline may facilitate an evaluation of receptor properties. Further studies now in progress show that in calf cerebellum the affinities of agonists are about 10-fold higher at sites labelled by <sup>3</sup>H-adrenaline than at sites labelled by <sup>3</sup>H-dihydroalprenolol, with the converse applying to antagonist affinities. These data suggest that a “two-state” model of receptor function may be applicable to the  $\beta$ -noradrenergic receptor as well as to the  $\alpha$ -noradrenergic and other receptors in the central nervous system<sup>6,8</sup>, although the differences between receptor interactions of agonists and antagonists are less marked at  $\beta$ -receptors than at other transmitter receptors. The possibility of labelling both  $\alpha$ - and  $\beta$ -receptors in the same tissue with the same <sup>3</sup>H-ligand may prove valuable in attempts to differentiate the properties of these two types of noradrenergic receptors.

This work was supported by an USPHS grant and a RSDA award to S.H.S. and an USPHS fellowship award to D.C.U.P. We thank P. Sheehan for technical assistance.

## Purine and pyrimidine mononucleotides depolarise neurones of explanted amphibian sympathetic ganglia

ADENINE nucleotides and nucleosides have been proposed as neurotransmitters<sup>1-3</sup>, in part based on their ability to inhibit spike activity in several peripheral<sup>1,4,5</sup> and central<sup>2,5,6</sup> sites. Only one preliminary study<sup>2</sup> has utilised intracellular recording to determine mechanisms of action of the purines in neurones. Because of their large size and simplified input-output relationships, neurones of sympathetic ganglia are a favourable model for intracellular recording. Although several studies have shown effects of ATP on peripheral ganglia<sup>7,8</sup>, none utilised intracellular recording nor checked specificity of responses with other purine and pyrimidine

nucleic acid components. Therefore, we examined the effects of several purine and pyrimidine derivatives by intracellular recording of bullfrog sympathetic neurones in explant cultures. Our findings show pronounced depolarisations with the di- and triphosphoribo derivatives of several pyrimidine and purine bases, with the uridine nucleotides emerging as the most potent of all the compounds.

We studied 182 sympathetic neurones, cultured from adult bullfrogs and impaled with glass micropipettes (3 M KCl or potassium acetate; 8-40 MΩ impedance) under Nomarski optics. Intracellular stimulation was carried out by a bridge method<sup>10</sup> and current/voltage curves were constructed with a PDP-12 computer. The neurones studied ranged in size from 24 to 85 μm (long dimension) and displayed steady resting potentials of -35 to -58 mV with spike overshoots up to 30 mV or more. Drugs were applied by current-neutralised iontophoresis<sup>11</sup> or by rapid perfusion through a multiple valve system and a culture chamber with a volume of 0.3 ml.

Prolonged depolarisation was the predominant response to all the nucleic acid components studied, whether applied by perfusion or iontophoresis (Fig. 1a, b, d and e). Occasionally (14 of 98 cells) a long hyperpolarising component followed the depolarisations (Fig. 1c). In general, for any one purine or pyrimidine, the di- and tri-phosphonucleotides were equipotent as depolarising agents and more potent than their 5' monophosphonucleotides. The nucleosides guanosine, inosine and uridine and the heterocyclic bases guanine, adenine and uracyl were ineffective at concentrations up to 1-2.5 mM. Adenosine depolarised six of eleven neurones weakly at 2.5-5 mM.

Of all nucleotides studied, 5' uridine di- and triphosphate (UDP and UTP) were the most potent with thresholds for

**Fig. 1** Intracellular records of effects of mononucleotides on neurones cultured from the 8th-10th sympathetic ganglia of adult bullfrogs. Ganglia, cut into several pieces and placed on collagen coated coverslips, were cultured<sup>9</sup> for 1-3 months at 22 °C in the medium of McMahan and Kuffler<sup>14</sup>, also containing 0.3% methocel, streptomycin 100 μg ml<sup>-1</sup>, glutamine 0.8 mM, and usually, NGF 1 U ml<sup>-1</sup>. Heavy baselines in records show membrane potential (small numbers at beginning of each trace = mV). Light deflections below the baseline are responses to hyperpolarising constant current pulses of 0.05-1 nA and 200 ms duration, delivered through a Wheatstone bridge at 1 Hz. Examples of individual responses to current at higher polygraph speed below panel e. Pulses of 200 ms were used since this surpasses by 50-100 ms the initial unstable rectifying period typical of sympathetic neurones. Light lines above baseline are local depolarising responses to termination of current pulses (anodal break), which can trigger spikes. Heavy line descending below baseline every 20 s measures electrode resistance (1 MΩ/1 mV) by means of an RC circuit/ramp-input separate from the bridge circuit. a, Depolarising response to perfusion of ATP 5 × 10<sup>-5</sup> M, with production of anodal break spikes. b, Extracellular iontophoresis of UDP (0.2 M pH 6-7 in pipette) by anodal current of 60 nA depolarises another neurone with spiking. c, Another neurone: perfusion of UTP 5 × 10<sup>-5</sup> M causes depolarisation followed by a long hyperpolarisation; both phases accompanied by increases in input resistance, as assessed by size of hyperpolarising responses to constant current pulses, and increases in anodal break responses. d, Dose-related depolarisations of one neurone to UTP. e, Another cell: UTP 5 × 10<sup>-5</sup> M depolarises cell with intense spiking; high speed excerpts taken from this record at times indicated by arrows show multiple anodal-break spikes and an increase in input resistance during depolarisation; bar below record indicates time for high speed records. f, Same cell as e: UTP causes anodal-break spiking even while membrane potential is held at resting level by injection of continuous hyperpolarising current; calibration bar in upper right corner applies to all records except high speed excerpts of panel e.

depolarisation of about  $10^{-8}$  to  $5 \times 10^{-8}$  M; UTP  $5 \times 10^{-5}$  M produced depolarisations of 4–19 mV (mean = 10 mV;  $n=40$ ). Dose-related responses are shown in Fig. 1d. Thresholds for 5' ATP and 5' ADP were about  $10^{-6}$  to  $10^{-7}$  M; ATP  $5 \times 10^{-5}$  M depolarised an average of 5 mV ( $n=26$ ). Thymidine di- and triphosphate, guanosine di- and triphosphate and inosine di- and triphosphate were roughly equipotent with ATP. The uridine nucleotides seemed most potent also when applied by iontophoresis, producing depolarisations up to 16 mV; ATP and ADP evoked smaller depolarisations (up to 10 mV) with similar currents. Adenosine by iontophoresis was ineffective. Of all the nucleotides tested by perfusion, only 5' cytidine tri- and diphosphosphate were ineffective or only weakly active at  $5 \times 10^{-5}$  M. Pyrophosphate, 2'-deoxy-ATP, uridine diphosphoglucose, and D-ribose 5' phosphate were largely ineffective at concentrations ( $5 \times 10^{-5}$  to  $10^{-4}$  M) which were maximally effective for the nucleotides.

Both the depolarisations and the occasional ensuing hyperpolarisations were generally accompanied by an increase (47 out of 65 cells) or no measurable change in input resistance, as determined either by measuring responses to hyperpolarising constant current pulses (Fig. 1e), or by comparing current/voltage curves (Fig. 2). Only five cells showed resistance decreases. Preliminary tests of voltage dependence showed that the size of the nucleotide depolarisation was inversely related to membrane potential (two cells) or was not affected (two cells) by changes in membrane potential from -70 to -6 mV.

Changes in spike generation (produced by intracellular stimulation) also occurred during the nucleotide responses. Most commonly, thresholds for spiking decreased (Fig. 1a, b, d, e and f) during the initial phases of depolarisation (40 out of 69 cells), although occasionally thresholds

increased during the later phases. A pure increase in spike threshold occurred in 10 of the 69 cells. The nucleotide-evoked increases in resistance and spiking are not dependent on the depolarisations, since they are not diminished by holding the membrane potential at resting level with current during perfusion of the mononucleotide (Fig. 1f). Further, depolarising the membrane by current to the same level as evoked by the nucleotide had no equivalent effect on spiking and resistance.

The mononucleotides act like the muscarinic cholinergic agent muscarine, which also depolarises cultured sympathetic neurones with increases in input resistance (G.R.S., D.L.G., A.L.P., and D.S.F. unpublished). The possibility that the nucleotides act by releasing endogenous acetylcholine, however, seems unlikely, since total blockade of the muscarine response by high concentrations of atropine ( $3 \times 10^{-6}$  to  $1.3 \times 10^{-5}$  M) has no effect on the responses to the uridine or adenine mononucleotides (six out of six cells). Perfusion with nicotine  $2.5$ – $5 \times 10^{-3}$  M (eight cells), (+)-tubocurarine 1 mM (four cells), or high  $Mg^{2+}$  (10–20 mM), low  $Ca^{2+}$  (0.5–1 mM) concentrations (six cells) also has little effect on the nucleotide responses. The fact that local application of UTP, UDP, ATP and ADP by iontophoresis markedly depolarised neurones, also argues for a direct effect of the nucleotides.

In preliminary studies, neither physostigmine ( $5 \times 10^{-5}$  M), hexamethonium (0.5–2.5 mM), phentolamine ( $10^{-4}$  M) nor sotatol ( $1.5 \times 10^{-4}$  M) altered responses to the nucleotides. Only quinidine ( $5 \times 10^{-4}$ ) blocked the UTP or ATP responses. This antagonism is, however, relatively unspecific, since the effects of muscarine are also blocked. The nucleotide receptor is not equivalent to the adenosine receptor of brain<sup>5,12</sup>, since in our preparation methyl xanthines (2.5 mM) do not antagonise, but in fact occasionally potentiate responses to the mononucleotides. This might indicate mediation of the response by intracellular cyclic nucleotides. Perfusion of high concentrations of either cyclic AMP ( $10^{-3}$ – $10^{-2}$  M), cyclic GMP ( $5 \times 10^{-3}$  M) or cyclic UMP ( $10^{-3}$  M), however, had only weak and variable effects on membrane potential, perhaps because of poor cell penetrability by the cyclic nucleotides. Finally, calcium chelation would not seem to be a factor in the nucleotide responses since such low effective concentrations of the nucleotides ( $10^{-7}$ – $10^{-8}$  M) are not likely to stoichiometrically remove significant  $Ca^{2+}$  from the Ringer's solution (containing 2 mM  $Ca^{2+}$ ), and since  $Ca^{2+}$  removal does not reduce the responses.

The potent responses to several of the mononucleotides might indicate their function as neurotransmitters in so-called 'purinergic' nerves or as 'co-transmitters' which might be released with acetylcholine or noradrenaline from autonomic nerves. In our preparation, the generalised effectiveness of purine and pyrimidine mononucleotides suggests that the 'purinergic' label may be too restrictive, especially since the uridine nucleotides are the most potent. In the *Torpedo* electric organ cholinergic stimulation releases ATP postjunctionally<sup>13</sup>. Our results suggest that such release could modulate or even mediate the response to a neurotransmitter. Indeed, responses to the nucleotides bear a strong resemblance to the ganglionic late slow excitatory postsynaptic potential, which is also atropine resistant. Preliminary results show that iontophoresis of UDP and UTP increases firing rates of several types of rat central neurones *in situ* (G.R.S. unpublished). Taken with the present finding of a potent depolarising action of uridine nucleotides in cultured sympathetic neurones, these results suggest that the uridine nucleotides warrant close scrutiny for their possible involvement in neurotransmission.

**Fig. 2** Changes in current/voltage relationships of cultured sympathetic neurone in response to ADP. Curves were generated on-line by PDP-12 computer (DEC) using a modified ADTAPE program and FOCAL programs which select and average five consecutive digital points in equivalent control and pulse periods (200 ms duration) for current and voltage. During the current pulse, points were only sampled after the membrane potential had reached a steady level, generally 120–150 ms after pulse initiation (see high speed pulse records of Fig. 1e); care was taken to avoid selection of points where spikes occurred. ○, Control period; ●, peak of depolarisation to ADP  $10^{-4}$  M; X, peak of subsequent hyperpolarisation to ADP (see text). Increase in slopes of the latter two lines indicate increase in input resistance during both the 8 mV depolarisation and the 2.5 mV hyperpolarisation to ADP. Control input resistance = 16 MΩ.

## Sodium channels in nerve apparently have two conductance states

THE inward sodium current underlying the nerve action potential is carried by discrete Na channels<sup>1</sup> in the membrane which are gated in response to the membrane potential. A basic question in understanding the gating mechanism is whether the conductance of the channels has only two states, open and closed, or whether there are more states, with the channel conductance progressing from one level to another to give the variable membrane conductance observed in voltage-clamp experiments. The ensemble fluctuation measurements reported here are consistent with the simple interpretation that Na channels have only two principal conductance states, with conductances of 0 and  $7.7 \pm 1$  pS (near zero membrane potential), and number approximately  $5 \times 10^4$  in the node of Ranvier of a 14  $\mu$ m diameter frog myelinated nerve fibre. Like stationary fluctuation analysis<sup>2</sup>, the experimental method described here can yield information about the size and kinetics of the single gating events in ionic channels, but is also applicable to non-stationary processes such as membrane conductances that activate or inactivate with time. I report here measurements of the mean Na current and the variance at various times after the start of a depolarising pulse, using an ensemble of successively evoked current transients.

The preparation used was *Rana temporaria*, node of Ranvier; this is useful for fluctuation experiments because a stable voltage clamp with low background noise is readily obtained and because the number of Na channels is in a convenient range ( $\lesssim 10^5$ ). Experiments were carried out at 2 °C to maximise the ratio of current fluctuations to thermal noise amplitude, and the voltage clamp electronics included a provision for measuring the membrane capacitance and the passive resistances of the intact preparation, allowing the thermal noise background to be estimated reliably. Potassium currents were blocked with internal Cs and external tetraethylammonium ions, and linear leak subtraction was used. A set of 64–160 Na current transients was elicited by repetitively depolarising the membrane at intervals of 300–500 ms. From groups of eight successive current records,

**Fig. 1** Ensemble variance calculation. *a*, Eight current records aligned with the start of the depolarising pulse (arrow). *b*, Residual fluctuations from each record after subtracting the mean of eight. *c*, Ensemble variance estimated from 72 records by the following process: the sum of the squares of the fluctuations was calculated for each time point; the resulting set of squared deviations was scaled and averaged with eight others; finally, the estimated background was subtracted. Each bar represents the mean of the resulting values at four adjacent time points. The smooth curve is the mean current record, scaled by a factor of  $-0.3$  pA. Node 13. Bathing Ringer solution contained 20 mM TEA-Cl; cut internodes were in 110 mM CsCl, 10 mM NaCl. Current records low-pass filtered at 5 kHz (4 pole, Gaussian response) and digitised (12 bits, 256 samples per record) at 100  $\mu$ s intervals; aperture time jitter was  $< 50$  ns. The thermal noise background was calculated (equations 11–16 of ref. 6) for each current sample, using the measured values for the internode and seal resistances and making use of the instantaneous *I-V* relation in estimating the membrane slope conductance. The peak value of the background component of the variance in *c* was  $7 \times 10^{-22} A^2$ .

mean and variance records were calculated point-by-point using a procedure similar to conventional signal averaging (Fig. 1). Several of these variance records were in turn averaged, and the conductance-dependent contribution from thermal and instrumental noise was calculated and subtracted, to yield an ensemble variance record. Figure 1c shows that the ensemble variance is proportional to the mean current at low conductance levels, but seems to saturate during the phase of high membrane conductance.

The contribution to the variance from processes other than channel gating was examined in several ways. First, the variance measured at  $V_0$ , the reversal potential for Na current, was found to be accounted for (within an uncertainty of  $2 \times 10^{-22} A^2$ ) by the calculated thermal noise background. Secondly, long term changes in the amplitude of Na current were monitored and were found to be  $< 2\%$  after 160 depolarisations in the experiments reported here. Because the mean and variance were calculated from small groups of successive records, linear drifts of that magnitude would not contribute significantly to the variance. Finally, the functional relationship between the variance and mean current values provides a clue to the source of the fluctuations. Any process which perturbs the properties of all the channels in the membrane coherently (for example, temperature or voltage fluctuations) would probably result in current fluctuations with variance increasing with the square of the mean current. Fluctuations in the transport of ions through

open channels would also be expected to give a monotonically increasing variance with increasing membrane conductance. Instead, the variance saturates and even decreases at high membrane conductance (Fig. 2), suggesting that neither of these processes is the predominant source of the fluctuations.

If the fluctuations were entirely due to Na channel gating, they could be interpreted on the basis of a simple open-closed scheme for the conductance of each channel. Assuming that the Na current is carried by a homogeneous population of  $N$  channels which are gated in a statistically independent fashion, the mean current  $I$  and the variance  $\sigma_i^2$  would be given by<sup>3</sup>

$$I = Npi$$

$$\sigma_i^2 = Np(1-p)i^2$$

$$i = \gamma(V - V_0)$$

where  $i$  is the current carried by a single channel,  $\gamma$  is the single-channel conductance,  $V$  is the membrane potential and  $V_0$  the reversal potential. The probability that a channel is in its open state is given by  $p$ , which is a function of both membrane potential and time. This theory assumes two conductance states but makes no assumption about the kinetics or voltage dependence of the gating process. A more specific theory based on the Hodgkin-Huxley equations would have  $p = m^3h$ .

The predictions of the two-state theory were tested in three ways. First, the relationship between  $I$  and  $\sigma_i^2$  was observed as  $p$  changes with time during each depolarisation. Plots of these quantities (Fig. 2) were fitted with the predicted quadratic function, and data obtained with different depolarisations of the same node could be fitted with the same value of  $N$ . Second, the voltage dependence of the single-channel current  $i$  was compared with the 'instantaneous' current-voltage relation of the membrane as determined by a voltage-jump experiment (Fig. 3). The values of  $i$  (estimated by curve fitting as in Fig. 2) represent either the single-channel current of the two-state

**Fig. 2** Variance plotted against the absolute value of mean current, with the time after the start of each depolarising pulse as the independent parameter. Points farthest from the origin correspond to the peak Na conductance. Depolarisations to  $-35$  and  $5$  mV (node 14) and  $125$  mV (node 8), all with  $-105$  mV,  $50$  ms prepulse from holding potential of  $-80$  mV. Theoretical curves drawn with  $N = 5 \times 10^4$ ;  $i = -0.7$ ,  $-0.31$ , and  $0.2$  pA, respectively.

**Fig. 3** Comparison of single channel currents and instantaneous  $I-V$  relation. Single channel currents from nodes  $\diamond$ , 8;  $\circ$ , 12;  $\triangle$ , 13;  $\square$ , 14. Curve follows instantaneous current values ( $\bullet$ ) from node 8, measured at the potential indicated after a 2 ms prepulse to  $V_0 = 44$  mV.

scheme or a weighted average of the various current levels in a multiple state scheme<sup>2</sup>. The similarity in voltage dependence argues against multiple state schemes in which the distribution among states of different conductance is voltage dependent.

Third, values of  $\gamma$  were estimated under conditions which modify the peak Na conductance of the membrane. Pre-pulses in the range  $-105$  to  $-55$  mV changed the peak conductance by a factor of 4 but caused no significant change in  $\gamma$ . Treatment with 8 nM tetrodotoxin reduced the currents by a factor of 5 but also left  $\gamma$  unchanged. Changing the Na concentration or the pH of the solution bathing the node changed  $\gamma$  from the control value of  $7.7 \pm 1$  pS measured at 0 mV in 90 mM Na to  $4.1 \pm 1.2$  pS in 55 mM Na and to  $2.5 \pm 1$  pS at pH = 5.2. Hydrogen ions are thought to alter the ion transport through open Na channels<sup>4,5</sup>.

Although this estimate of  $\gamma$  is similar to another measurement from nodes of Ranvier<sup>6</sup>, it may have been affected by the presence of transport noise or excessive filtering. An upper limit on the effect of transport noise can be estimated if all of the channels are assumed to be open at the peak conductance at 125 mV (Fig. 2). The variance in the peak current would then be entirely from transport fluctuations in open channels. Assuming the transport noise variance increases linearly with the Na conductance, this excess variance would cause my estimate of  $\gamma$  to be higher than the actual value by at most 40%. Alternatively,  $\gamma$  would have been underestimated if a step in the gating process has a relaxation time  $\leq 30$   $\mu$ s, for part of the resulting fluctuations would have been filtered. The estimates of the total number of channels  $N$  were in the range of  $3-6 \times 10^4$ , which corresponds to a Na channel density in the nodal membrane of roughly  $1,000 \mu\text{m}^{-2}$ . These values are tentative because the pool of channels that  $N$  represents may (because of ultraslow inactivation<sup>7</sup>, for example) be smaller than the total population in the membrane.

This work, like previous tests of the two-state theory<sup>6</sup>, has not ruled out all multiple conductance state schemes; there are theories with multiple conductance states which give predictions similar to those of the two-state theory. The simplest interpretation, however, is that Na channels have only two states of conductance.

I thank Dr C. F. Stevens for his encouragement. This work was supported by a grant from the NIH to Dr Stevens.

## Modulation of electrical activity in *Aplysia* neurones by cholesterol

VARIOUS hormones and drugs induce long-lasting alterations of electrical activity in certain neurones from the marine snail *Aplysia californica*<sup>1–5</sup>. Drugs and hormones were found to affect the lipid microviscosity of biological membranes<sup>6,7</sup>, so it is plausible that their effect on electrical activity is mediated by changes in membrane fluidity. We report here that by changing the cholesterol content of *Aplysia* neurones, which presumably increases its membrane microviscosity<sup>8</sup>, long term, though reversible, alterations in electrical activity are induced.

In all experiments the visceral ganglion of *A. californica* was removed and the cell bodies were exposed by microdissection of the connective tissue. Microelectrodes filled with 3 M KCl were inserted into a neurone and its electrical activity was monitored using standard intracellular recording techniques<sup>9</sup>. Sonicated liposomes were used as exogenous pools for enrichment or depletion of the cell membrane cholesterol<sup>10,11</sup>. For preparation of cholesterol-rich liposomes 160 mg of egg lecithin (Sigma type VE) and 100 mg of cholesterol (Sigma CHS) in chloroform were mixed in a sonication vessel and evaporated to complete dryness under argon. Ten ml of seawater was added and the mixture subjected to 70 W ultrasonic irradiation (Branson Sonifier W350) for 60 min at 0 °C in an argon atmosphere. The liposomal dispersion was then centrifuged at 60,000g for 20 min and the bottom and upper layers were discarded. The middle layer, which presumably consisted primarily of single walled liposomes<sup>12</sup>, was used in the cholesterol enrichment experiments. For cholesterol depletion, liposomes of egg lecithin (160 mg in 10 ml seawater) were prepared analogously to the lecithin-cholesterol liposomes.

A freshly prepared liposome suspension was diluted 1:4 (v/v) in seawater and then applied to the ganglion by perfusion during continuous electrical recording for up to 3 h. In a series of 17 independent experiments perfusion of pacemaker and burster type neurones with lecithin-cholesterol liposomes was always found to gradually inhibit the spontaneous electrical activity of the neurones after a 4–10 min lag. After further 10–30 min all spontaneous activity ceased (Fig. 1a). Simultaneously, the threshold to elicit an action potential following intracellular stimulation progressively increased, in some cases reaching the stage where an action potential could not be produced by intracellular stimulation. Both the resting membrane potential and the steady-state slope conductance ( $\Delta I/\Delta E$ ) of the *Aplysia* neurones were apparently not affected by the lecithin-cholesterol perfusion. When active neurones were perfused with lecithin liposomes, no decrease in activity was observed.

For estimation of the rate of cholesterol uptake analogous liposomes made from egg lecithin and <sup>3</sup>H-cholesterol were prepared and applied separately to four isolated ganglia of similar size. The treated ganglia were thoroughly washed after 5, 15, 30, and 60 min of incubation, respectively, dissolved in a tissue solubiliser (NCS, Amersham) and then counted in a scintillation counter. Because of the large excess of the exogenous cholesterol in the incubation medium the rate of cholesterol depletion was considered as negligible compared to the rate of cholesterol uptake by the cells, which is therefore proportional to the accumulated radioactivity. The results showed a progressive uptake of cholesterol at a rate of approximately 300 pmol per h per ganglion. Assuming that the ganglion is composed of  $2 \times 10^3$  cells averaging about 200  $\mu$ m in diameter<sup>13</sup> which are partially exposed to the lecithin-cholesterol liposomes, and that the remaining glia cells do not interfere with the cholesterol uptake, then the observed rate of

cholesterol enrichment is of the same order of magnitude as in blood cells.<sup>10</sup>

The spontaneous electrical activity of the cholesterol-enriched neurones could be restored on subsequent perfusion with lecithin liposomes for less than 30 min (Fig. 1a,b). This treatment, which presumably depletes the membrane cholesterol in a similar fashion to that observed in other cells<sup>10,11</sup>, demonstrates that the effect of cholesterol is reversible and passive. In some cases, the restored spontaneous electrical activity lasted until the electrode was withdrawn (over 1 h). In other experiments, however, spontaneous activity ceased after 10–20 min without affecting the capacity of the neurone to produce an action potential after intracellular stimulation. Furthermore, perfusion with lecithin liposomes of *Aplysia* neurones which were initially silent, generated continuous action potentials similar to pacemaker activity (Fig. 1c) which in most cases lasted until the experiment was terminated (over 1 h).

**Fig. 1** Effect of liposome treatment on electrical activity of *Aplysia* neurones. *a*, Perfusion with lecithin-cholesterol liposomes ( $4 + 2.5$  mg ml<sup>-1</sup> in seawater) (commenced at arrow) caused spontaneous activity to cease. The ganglion was then washed in seawater and perfused with lecithin liposomes ( $4$  mg ml<sup>-1</sup> in seawater) which progressively restored electrical activity. The spontaneous activity was not maintained in this case. *b*, An identical experiment to (*a*) but with a separate ganglion. The response to a constant intracellular stimulation between the wash and after treatment with lecithin is shown. In this case, the restored spontaneous activity continued over 1 h when the electrode was withdrawn. *c*, Treatment with lecithin liposomes ( $4$  mg ml<sup>-1</sup> in seawater) of an initially silent neurone. The activity continued until the experiment was terminated (over 1 h). All experiments were carried out at 25 °C.

One of the main factors which determine the lipid microviscosity of cell membranes is the mole ratio of cholesterol to phospholipids (C/PL). In *in vitro* conditions this determinant can be modulated by treatment with liposomes by two main mechanisms. First, in the translocation mechanism, cholesterol molecules partition between the lipid pools of the liposomes and the membrane towards equilibration of their C/PL levels. This takes place in treatment of erythrocytes<sup>10</sup>, lymphocytes<sup>11</sup> and platelets<sup>14</sup> with liposomes of various C/PL. Second, the fusion mechanism, involves integration of the liposomes by fusion with the cell membrane<sup>15</sup>, presumably through specific receptors<sup>16</sup>. The fusion mechanism was demonstrated in a series of cells including lymphocytes<sup>17</sup> and fibroblasts<sup>18</sup>. In general, these two mechanisms do not affect the viability of cells and eventually lead to a similar change in C/PL of the cell membrane. Because of technical difficulties, we have been able to establish which mechanism operates in the perfusion of the *Aplysia* neurones with liposomes.

The common methods for measurements of membrane microviscosity<sup>8</sup> could not be applied to the isolated *Aplysia* ganglia. But, it is reasonable to assume that, as for most other cell membranes, enrichment with cholesterol markedly increases the microviscosity<sup>8</sup>, as well as the degree of exposure of membrane proteins<sup>19</sup>, and decreases the turnover of individual membrane enzymes and transport channels. The net effect of these modulations is expressed in alterations of cellular activity<sup>20</sup>. The findings presented here suggest that the activity of membrane sites, which are associated with spontaneous electrical activity and generation of action potential, is also dependent on membrane fluidity as determined by the cholesterol level. In principle, decrease in membrane fluidity can also be achieved by reducing the temperature. It has been previously shown<sup>2</sup> that by lowering temperature, the activity of *Aplysia* neurones is reduced, but to a lesser extent than with cholesterol enrichment. Possible alteration of the Na, K ATPase activity in the cholesterol enriched membrane<sup>21,22</sup> could be one of the factors which mediate the observed changes in electrical activity. As the resting membrane potential was not affected by the cholesterol enrichment or depletion, however, it seems that the electrogenic Na, K pump, which exerts a tonic contribution to the membrane potential in *Aplysia* neurones<sup>23</sup>, is not noticeably affected by membrane fluidity. Alteration in internal Ca activity could also contribute to the observed effects<sup>24,25</sup>. The lack of substantial changes in conductance and resting membrane potential upon enrichment with cholesterol suggests, however, that the major effect is on the channels and gates which are essential for action potential production<sup>26</sup>. Since the action potential height decreases during cholesterol treatment (Fig. 1b), and in some cases after prolonged perfusion only a small spread-out regenerative response could be elicited, it seems that inclusion of cholesterol decreases the active inward conductance. For a better understanding of the effect described here, voltage clamp and ion selectivity experiments are required.

The microviscosity of biological membranes may vary in various physiological and pathological conditions<sup>27</sup>. Neuroblastoma cells have been shown to undergo a marked modulation in membrane microviscosity during their cell cycle<sup>28</sup>. On differentiation of these cells the membrane fluidity is increased and this process can therefore be blocked by cholesterol enrichment<sup>29</sup>. By changing the lipid composition of neuroblastoma cells conspicuous morphological changes have been also observed<sup>30</sup>. Such changes may also occur in other nerve tissue, and may induce a significant alteration of neuronal activity *in vivo*.

We thank Dr P. Henkart for his support, Dr W. Terry for useful comments and Dr D. Carpenter for use of aquarium facilities.

## Asymmetry of phospholipid biosynthesis

THE asymmetrical distribution of phospholipids in the membrane of the red blood cell<sup>1–3</sup> and other membranes<sup>4,5</sup> is well documented. How this asymmetry arises in these membranes is an obvious question which remains unanswered. One explanation is that the enzymes that catalyse the last step in the synthesis of the phospholipids are unevenly distributed on both sides of the membrane where biosynthesis occurs. The phospholipids that are produced by these enzymes would be released on to each side of the lipid bilayer and thus account for lipid asymmetry. A necessary corollary would be that this asymmetry of the phospholipids would be preserved in the movement of lipids to other membranes in the cell. Initial reports on the lack of transbilayer movement of phospholipids in artificial membranes<sup>6,7</sup> and membranes of animal viruses<sup>8</sup> has made an uneven distribution of phospholipid biosynthetic enzymes an attractive hypothesis. Recent reports, however, have documented the transbilayer movement of phospholipids in the red blood cell membrane<sup>9–11</sup> and the membrane of *Bacillus megaterium*<sup>12</sup>. Although the mechanism for this transbilayer movement of phospholipids has yet to be elucidated, it is no longer necessary to explain lipid asymmetry by the uneven distribution of the phospholipid biosynthetic enzymes on both sides of the membrane. We summarise here our evidence that the enzymes that help to produce phosphatidylcholine and phosphatidylethanolamine are located exclusively on the cytoplasmic surface of the endoplasmic reticulum of rat liver and not on both sides of the membrane.

Subcellular fractionation of rat liver yields a microsomal fraction which consists largely of sealed fragments from the endoplasmic reticulum<sup>13</sup>. These vesicles retain the asymmetry of the endoplasmic reticulum as it exists in the cell; the exterior of the microsomal vesicles corresponds to the cytoplasmic surface of the endoplasmic reticulum, whereas the luminal surface is the interior of the microsomes<sup>13</sup>. Preparation of microsomes with the opposite orientation has not been reported.

A rapid method for evaluation of the permeability and orientation of microsomes by measurement of the latency of mannose-6-phosphatase has been reported<sup>14,15</sup>. The enzyme that hydrolyses mannose-6-phosphate is located inside the microsomes, which are apparently impermeable to low concentrations (1 mM) of this substrate. Treatment of microsomes with 0.4% taurocholate allows the substrate to penetrate the vesicles<sup>14</sup>. Thus, by assay of the mannose-6-phosphatase before and after treatment with taurocholate, one can assess the orientation and intactness of the membrane of the microsomal vesicles. The latency of this enzymatic activity is defined as the "activity in disrupted microsomes minus activity in untreated microsomes/activity in disrupted microsomes"<sup>15</sup>.

Microsomes from rat liver were prepared as described by Nordlie and Arion<sup>16</sup>, except that homogenisation was in 0.145 M NaCl and contaminating cytoplasmic enzymes were removed by passage of the microsomes once through a discontinuous sucrose gradient<sup>17</sup>. The microsomes were suspended in 0.145 M NaCl at approximately 7 mg protein ml<sup>-1</sup> and stored at -70 °C. The latency of mannose-6-phosphatase in all preparations was greater than 90%. The activities of CDP-choline:1,2-diacylglycerol cholinephosphotransferase and CDP-ethanolamine:1,2-diacylglycerol ethanolaminephosphotransferase were assayed essentially as described by Kanoh and Ohno<sup>18</sup>. The assays of cholinephosphate cytidyltransferase<sup>19</sup> and phosphatidylethanolamine-S-adenosylmethionine methyltransferase<sup>20</sup> followed published procedures.

In our initial experiments with the cholinephosphotransferase (which condenses CDP-choline and 1,2-diacylglycerol to form phosphatidylcholine), we found that treatment of the microsomes with 0.4% taurocholate resulted in a sixfold increase in the cholinephosphotransferase activity (from 3.3 to 19 nmol per min per mg protein). We did not know if this increase in enzyme activity were due to stimulation by the detergent or the expression of latent activity localised on the interior of the microsomes.

One approach for differentiation between these two possibilities was to digest the microsomes with a proteolytic enzyme and subsequently treat the microsomes with 0.4% taurocholate. Cholinephosphotransferase activity localised on the interior of the microsomes should survive this treatment. Rat liver microsomes (1.4 mg protein) were digested with bovine pancreatic trypsin (1 mg; Sigma), in 0.5 ml 50 mM Tris-HCl, pH 7.4, for 15 min at 30 °C. The reaction was stopped with the addition of 2 mg soybean trypsin inhibitor (Sigma). In control incubations the trypsin inhibitor was added before the trypsin, or isotonic saline was added instead of trypsin and trypsin inhibitor. Samples (0.18 ml) were removed and incubated with 20 µl 4% sodium taurocholate dissolved in 50 mM Tris-HCl, pH 7.4, or with buffer alone, for 30 min at 0 °C. The activity of cholinephosphotransferase was subsequently assayed. By this treatment the activity of the enzyme decreased from 19 to 0.5 nmol per min per mg protein. Since more than 97% of the cholinephosphotransferase was inactivated by trypsin, it seemed that none of the cholinephosphotransferase was localised on the interior of the microsomes.

It was important for us to demonstrate that during the trypsin digestion, the microsomes remained intact and impermeable to the trypsin. We therefore carried out an experiment in which the activity of the cholinephosphotransferase and the latency of the mannose-6-phosphatase were determined after incubation with trypsin for various times. The results in Fig. 1 clearly show that the latency of the mannose-6-phosphatase was not affected by the proteolytic digestion, whereas the activity of the cholinephosphotransferase was eliminated. Other studies have shown that the mannose-6-phosphatase is inactivated by trypsin in the presence of 0.4% taurocholate.

Similar studies were performed with CDP-ethanolamine:1,2-diacylglycerol ethanolaminephosphotransferase (which forms phosphatidylethanolamine), cholinephosphate cytidyltransferase (which forms CDP-choline) and phosphatidylethanolamine methyltransferase (which transforms phosphatidylethanolamine to phosphatidylcholine by the transfer of methyl groups from S-adenosylmethionine). The experiment in Fig. 1 shows that these enzymes are also inactivated by trypsin in conditions in which mannose-6-phosphatase activity is unaffected. It seems, therefore, that the enzymes that synthesise phosphatidylcholine and phosphatidylethanolamine are localised on the exterior surface of the microsomes.

There is an additional explanation of our results which should be considered. It is possible that the phospholipid biosynthetic enzymes extend across the bilayer of the microsomal membrane. Tryptic digestion of the part of the protein that is exposed to the exterior might inactivate the enzyme even if the active site were on the inside of the microsomal membrane. We are unaware of any example where there is this arrangement of a membrane-bound enzyme. Moreover, if the active site were on the interior of the microsomes, transport of the substrate into the microsomes must

Fig. 1 Effect of trypsin on the activity of phospholipid biosynthetic enzymes associated with microsomes from rat liver. Microsomes (5 mg) were incubated with 3.5 mg trypsin, 10 mM Tris-HCl, pH 7.4, at 30 °C for the indicated time. Soybean trypsin inhibitor (5 mg) was added to terminate the reaction (final volume 1.5 ml). Aliquots from each incubation mixture were used to assay for cholinephosphotransferase<sup>18</sup> (■), ethanolaminephosphotransferase<sup>18</sup> (□), cholinephosphate cytidyltransferase<sup>19</sup> (▲) and phosphatidylethanolamine methyltransferase<sup>20</sup> (△) activities. Intactness of the microsomes was determined by measurement of the latency of mannose-6-phosphatase<sup>14,15</sup> (●).

occur. We have been unable to detect transport into the microsomes of any of the substrates for these phospholipid biosynthetic enzymes.

We conclude from our experiments that the enzymes that synthesise phosphatidylcholine and phosphatidylethanolamine are located on the cytoplasmic side of the endoplasmic reticulum. Thus, the origin of lipid asymmetry does not result from an uneven distribution of these enzymes on both sides of the endoplasmic reticulum. It remains a moot question as to how lipid asymmetry originates and is maintained in biological membranes.

We appreciate the support of the MRC of Canada and the BC Heart Foundation. This work was carried out during the tenure of an Established Investigatorship of the American Heart Association (D.E.V.). Studentship awards from the NRC of Canada (S.B.F.) and Canadian Heart Foundation (P.H.L.) are gratefully acknowledged. We thank Dr Gerald Weeks for a critical evaluation of the manuscript.
